Six Sizes: From 35 to 150 gallons of milk per hour.

Above: The pinion shaft carrying the spindle-driving gear has two ball bearings shown at 1 and 2.

The spindle has two more shown at 3 and 4. The bearing assembly is illustrated below.

IT'S the combination of ball bearings at the four high speed points, and positive, automatic oiling that makes McCormick-Deering Cream Separators so easy to turn. Try the one on display at the McCormick-Deering agent's and see for yourself how easily and quickly you can make the bowl run full speed.

Examine the scientifically designed discs that skim warm or cold milk with maximum butter-fat recovery. And remember to take notice how readily the glossy japanned finish wipes clean.

Ask the McCormick-Deering agent near you to demonstrate, or write direct for full information

Conferences.

Conferences of the Agricultural Bureau will be held as under:—

Southern, August 20th, at Murray Bridge (Secretary, Mr. S. S. Jones).

Hills, August 28th, at Balhannah (Secretary, Mr. H. A. Spoehr).

Murray Mallee, September 30th, at Alawoona (Secretary, Mr. B. L. Finey).

Eyre Peninsula (Eastern), October 6th, at Kimba (Secretary, Mr. W. Hutchens).

Eyre Peninsula, October 8th, at Wudinna (Secretary, Mr. C. A. Newbon).

Non-irrigated Fruits Districts, November 4th, at Angaston (Secretary, Mr. K. Robinson).

Papers, questions, &c., for Conferences should be in the hands of the General Secretary, Agricultural Bureau, Adelaide, a fortnight before the respective dates stated above.

List of Probable Dates of Country Shows During 1930.

| Name. | Secretary. | Address. | Approx. Date of Show. |
|------------------------------------|---------------------|---------------------|-----------------------|
| Eudunda | C. R. Treloar . . | Eudunda | September 24th |
| Streaky Bay | R. A. Kay | Streaky Bay | October 1st |
| Blyth | E. E. Eckermann . | Blyth | October 1st |

| Lameroo | H. H. Perrin . . . | Lameroo | October 8th |
| Tarlee | H. E. Reed | Tarlee | October 8th |
| Wooroorra (Tarlee) . . | A. R. Reed | Riverton | October 10th |
| Pinnaroo | J. H. Dewhirst . . | Pinnaroo | October 15th |
| Clare | F. W. Knappstein . | Clare | October 18th |
| Central Yorke Penin. (Minlaton) | D. M. S. Davies . . | Minlaton | October 22nd |
| Mount Gambier | H. L. Kennedy . . | Mount Gambier . . | October 22nd and 23rd |
| Tatiara (Bordertown) | A. F. Baker | Bordertown | October 29th and 30th |

Secretaries of Show Societies are invited to advise the Editor of the dates of their Shows.

Effectiveness of Granulated Superphosphate.

"Is granulated superphosphate as effective as a fertiliser as the finely ground product?" Professor A. J. Perkins (Director of Agriculture), replying to this question at the Conference of Upper North Branches of the Agricultural Bureau, held at Tarcowie on July 17th, said that the answer to this question was decidedly no, on the understanding that in each case not only the water solubility of the phosphoric acid present was the same, but also that the physical properties of hardness and compactness was identical in either sample. He had added this proviso because lumpy or granulated super might consist of exceedingly hard unit particles or be made up of an aggregation of smaller particles which crumbled away very readily. The superiority of fineness of division might be illustrated as follows:—Any substance that was water soluble entered into solution in soil moisture at a rate which was governed by the surface area of each particle; the greater the surface area exposed, the greater the quantity of water soluble material which entered into solution in soil moisture. Again, for the same weight of material, the smaller the particles, the greater the surface exposed, not only to soil moisture present, but also to contact with the root system of young plants growing in its immediate neighborhood. This question of fineness of division was of greater importance in the case of supers than in that of readily soluble substances, such as nitrate of soda or sulphate of ammonia. The latter entered into solution almost

[CHAS. H. BEAUMONT (District Horticultural Instructor).]

---

With the exception of a few peach trees, pruning should have been completed, and all that remains to be done is to sharpen and put away the tools in readiness for next season. Care in the use of tools will prevent rust and the need of renewals.

This month is the latest in which the use of dormant treatment for fungous pests will meet with any success. Prevention means less cost, both in time and material. Winter treatment should not be given if there is any sign of buds swelling; this includes the washing of vines for anthracnose.

It is necessary to watch citrus trees for brown rot. Pick up all diseased fruit and burn it, and keep limbs up from the ground. Bordeaux mixture is helpful in preventing spread of brown rot, but it must not be used if trees are to be fumigated.

Peach and cherry aphid may be noticed at any time now, and the early broods should be destroyed at once. Tobacco is the remedy.

Cultivation is the best work the orchardist can do to assist his trees; the final ploughing should be done while the soil is in good order. Harrowing can well be left until the soil begins to dry on top; see that the soil is worked up close to the trees. If it is intended to use sulphate of ammonia, it can now be worked in lightly around the trees.

Strawberry beds need a lot of attention to get the best results; all weeds must be cleaned out and soil kept loose.

Tomato glasshouse work consists mainly in keeping the soil worked and free from weeds and diseased plants; it is also necessary to keep the ground outside in good order and free from weeds or other plants.

Spraying or dusting machinery should be tested to see that it is ready for use, so that no hitch occurs when it is needed; a delay of a few days may mean the loss of the crop.

## Growing more crops with the Fordson

**I**NCREASED crop production has been urged by Australia's Prime Minister and by State Premiers as being vital to the nation's prosperity. "Grow more wheat" was broadcast throughout the Commonwealth—and the response of Australian farmers has been magnificent. With the plea to grow more crops has been the call to reduce production costs, and efficient agriculturalists have realised that the solution is found in Fordson farming—power farming at lowest cost.

The Fordson has pioneered power farming in Australia, and in every corner of the Commonwealth to-day is working in the national service of increasing crop acreage and lowering crop production costs. The history of power farming in Australia is largely the history of the Fordson Tractor, for the Fordson has always been the lowest-priced tractor and by far the most economical to operate.

The New Fordson embodies many mechanical improvements, gives 36% more power, operates on kerosene or petrol, and is backed by Ford Service through 1300 service stations throughout Australia. Full particulars and descriptive literature of the New Fordson Tractor can be obtained from your nearest Authorised Ford Dealer.

## INQUIRY DEPARTMENT.

---

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Secretary Agricultural Bureau, Wasleys, reports unbroken colts that have difficulty in passing water.

Reply—I am of the opinion that the trouble is a digestive one. The following treatment is suggested:—(1) Drench affected colt (9-18 months) as soon as signs of illness are observed with following mixture:—Raw linseed oil, 6ozs.; turpentine, one tablespoonful. Mix thoroughly before giving. (2) Subsequently give a small level teaspoonful of powdered nux vomica three times during the day (morning, mid-day, and evening). Mix with treacle and smear on tongue. (3) Feed on a little long hay containing not too much grain for three-four days. If several foals are affected, the ~~foal~~ is at fault, and a change of feed will have to be made. Bran mashies are useful for regulating bowels.

"E. T. K.," Kilkerran, has cow stiff in hind quarters, in poor condition.

Reply—(1) Give the following drench:—Epsom salts, 1lb.; ginger, 4 tablespoonfuls; treacle, 1 cupful; warm water, 2 pints. (2) Subsequently give a level teaspoonful of powdered nux vomica night and morning for 10 days. (3) Supply bran in the ration and green stuff daily if possible. Further, mix four tablespoonfuls of sterilized sweet ground bonemeal in the damped feed daily for three-four weeks. All the cattle should be supplied with a mineral mixture. The following is recommended:—Finely ground Nauru rock phosphate, 2 parts; salt, 1 part.

"O. E. K.," New Residence, has mare continually rubbing herself on posts, &c.

Reply—The following treatment is suggested:—Starve horse for 18 hours, and at the end of that period give this drench:—Raw linseed oil, 1 pint; turpentine, 4 tablespoonfuls. Subsequently feed on good nourishing food, including a little crushed oats. Further, clip horse all over and take care of him after doing so by rugging at night, and if necessary stabling.

"E. Bros.," Karoonda, has horse, seven years, bad cough and foul smelling breath, appetite very poor.

Reply—Make a careful examination of the teeth for dental irregularities and any decaying teeth. If present, have them attended to. Further, the following treatment is suggested:—Starve for 18 hours, and at the end of that time give the following drench:—Raw linseed oil, 1 pint; turpentine, 4 tablespoonfuls. Subsequently feed good quality chaff (which should be damped) and bran. If possible, add a ~~few~~ crushed oats. If cough persists, give a tablespoonful of Fowler's solution of arsenic night and morning, mixed in a small damped feed, for 14 days.

"P. W. D.," Lucindale, asks (1) if it is advantageous to wash out an aged mare prior to service; and (2) treatment for cows eating fowl manure.

Replies—(1) The only object in so doing is to bring away any discharge or correct acidity, and nothing is to be gained in using any solution unless it is for such a specific purpose. The washing can be done two or three hours before service of the horse, using such solutions as baking soda, one tablespoonful to the pint of water; common salt, one heaped teaspoonful to the pint of water. "Baking" the mare (passing in the hand and arm into the womb) is often practised by men leading stallions, but is only effective where there is a catarrh of the organ, the object being the removal of the

(PATON)

discharge and stimulation of the organ. The commonest cause for barrenness in an aged mare is that through disuse the genital organs have atrophied. (2) Cows eating fowl manure. This is indicative of a deficiency of phosphates in their diet, and it is suggested that the quantity of the lick you are giving be increased by giving the same amount twice a day, and in addition, place some in a box to which the cattle can have access at any time. "Top" sheep and cattle lick, No. 1, would be quite as efficacious and cheaper to use.

"T. B. Z.," Mudamuckla, asks treatment for horse with strangles.

Reply—(1) Isolate the animal. The disease is highly contagious. (2) Keep warm and put on to bran mash and green feed. (3) Supply drinking water in bucket and put 2ozs. of Epsom salts in it. Change daily. (4) Do not drench. (5) Treat swollen throat as follows:—Apply a mustard plaster. Mix mustard with water to about same consistency as that used for the table, and rub this on both sides of the throat up to the roots of the ears and down between the jaws. (6) As abscess comes to a head apply hot fomentations or repeat mustard until it bursts. When this occurs syringe out with lysol solution (tablespoonful to a gallon). (7) If breathing is bad, steaming the head could be tried. (8) Do not return horse to work until fit and strong.

"H. J. C.," Chandada, asks if bluestone solution can be used for worms in horses.

Reply—Although rarely used for the purpose, copper sulphate can be used to kill worms in horses. If used, two drams of copper sulphate mixed with two drams of sulphate of iron are given in a ball, administered fasting, and repeated daily for a week. I take it that you are referring to the strength of copper sulphate solution, which is used for pickling purposes. This is a 1 per cent. solution. Two pounds of oats pickled in such a solution would contain approximately half dram or less of copper sulphate. Without experimenting it is difficult to say what action as a vermifuge this drug would have when given in this manner. It could be tried and the results would be of interest. The treatment as outlined by the inquirer should not be given for more than 10 days, as after this period copper sulphate may cause digestive disturbances.

"T. W.," Cleve, asks treatment for horse staked above the fetlock.

Reply—The history of the patient suggests that a portion of the stake is still in the part, or that an abscess is forming. *Treatment*.—Clip hair off leg adjacent to the original wound and apply hot foment (or a poultice) to the part. When the swelling comes to a head, it should be carefully opened with the point of a sharp penknife to establish good drainage. Then a warm solution of lysol (two tablespoonfuls to a pint of water) should be injected two or three times daily, and the wound searched for presence of piece of stake, &c. The swelling higher up the leg is due to abscess forming at site of original wound.

"E. H.," Moorlands, has horse with an injured fetlock discharging pus.

Reply—You do not state where the matter (pus) is coming from, i.e., whether from the heel or the fetlock. If from the heel, steps should be taken to make a careful inspection of the foot for the presence of a stake, nails, &c. If wound is on fetlock, apply hot foment two or three times a day, or a hot poultice (antiphlogistine is the best). Heel injuries often occur as the result of being trodden on by adjoining horses in a team when turning, and may become a serious condition owing to the lateral cartilage inside the hoof wall becoming injured. Treatment of this condition is by hot fomentations and bathing in hot disinfectant solutions.

"J. E. A.," Pinnaroo, reports cow giving a creamy curd from one quarter of the udder, with a hard lump in the teat.

Reply—The cow is affected with mammitis. When first noticed, it should have been given the same treatment as you are applying now. The quarter is now probably chronically affected, but the treatment that has been given should be still applied with the exception that camphorated oil should be used. Care should be taken that other quarters are milked out before attending to affected quarter. A cow should be dried off from six to eight weeks prior to calving.

"A. R. H.," Meribah, asks the advisability of using mustard as a cure for sand in horses when administered with flour and water and made into a pill.

Reply—The effect of mustard taken internally is that it helps digestion of food by increasing the blood supply to the stomach and causes the expulsion of gas from the bowels. For veterinary use it has sometimes been prescribed for old horses affected with chronic intestinal catarrh, combined with powdered nux vomica and Carlsbad salts, where there is diminished power in the bowels, but the principal use of mustard used internally is to stimulate gastric secretion. Mustard would not have any effect on lung functions.

"A. B. H.," Ceduna, reports horse that hangs its tongue out continually whilst at work and attempts to pass water.

Reply—The tongue lolling may be due to an abrasion in the mouth caused by dental irregularities. Or it may be due to the animal experiencing some difficulty in breathing when in draught. The repeated desire to urinate is probably just due to a reflex irritation of the bladder by pressure on it of overlying bowel distended with foodstuff, and it is probable that overloading of the bowels with food is responsible for a difficulty in breathing when at work. The following treatment is suggested:—Make an examination of the animal's mouth for dental irregularities; have same attended to. Give the animal a dose of physic to unload the bowels, and subsequently feed on more concentrated rations. See that the bowels are kept in good order and constipation prevented by giving a weekly bran mash or a daily allowance of green feed. If the animal tends to get his mouth well down on his chest when at work, it may be necessary to use an overhead check rein to keep his head in a more extended position.

"E. O. G.," Bordertown, reports horse continually rubbing its tail.

Reply—This may be due to two causes:—(1) Accumulation of dandruff and other debris at base of tail. (2) Presence of small worms (oxyurids) in the back passage. *Treatment.*—One of the places most generally overlooked in grooming is the base of the tail, and washing with warm water and soap is recommended. In the case of the cause being due to the presence of worms in the hind gut (rectum) which is generally denoted by switching of tail and a sticky, yellowish-colored deposit about the anus, the treatment is mainly given per rectum, and consists of the injection of either of the following solutions:—(1) Infusion of tobacco, 1oz. to the quart of water. (2) Three teaspoonfuls of lysol in 2 pints of water. These injections should be given through a piece of  $\frac{1}{4}$  in. hose with a funnel inserted in one end. Previous to the injection of either of the above solutions, the bowel should be emptied by an injection of glycerine in water, or warm soapy water. Repeat the treatment at intervals of six days, and keep the anus free of the yellowish deposit until indications prove that worms have disappeared. The administration of a purgative drench of raw linseed oil, 1 pint; oil of turpentine, 2ozs., is also of assistance in expelling worms which are present in gut, but out of reach of the rectal injections, and should be given after starving the horse for at least 12 hours.

"G. F.," Wilmington, asks for particulars of the disease "red-water" in cattle.

Reply—This condition is of varying types such as:—(1) Tick fever (not present in South Australia).—Common in Queensland. The diagnostic symptom is the passing of bloody-colored urine. (2) Parturient "Red-water."—Occurs from a few days to several weeks subsequent to act of calving and characterised by frothy urine which as disease progresses assumes a smoky tint, changing later to red and finally to deep porter color. (3) A specific type of "red-water" associated with growths in the bladder is found around Mount Gambier area. It has never been observed in any other part of South Australia. (4) "Red-water" in cattle may also be due to calculi injuries, &c. (5) Another type of "red-water" has occasionally been reported in this State and in Victoria. It is not associated with parturition. Affected cattle are poor in condition, and urine becomes dark brown in color. It is believed to be associated with the type of pasture on which cattle are feeding. Recovery usually takes place in about seven days. This last type of "red-water" is probably the form reported to me from your district. The following treatment is recommended for it:—(1) Give following drench early:—Sodium chloride, 12ozs.; thin linseed gruel, 4 pints; treacle, 2lbs. (2) Subsequently give the following powder twice daily for three to four days mixed in the feed:—Magnesium sulphate, 1oz.; sulphur sub.,  $\frac{1}{2}$ oz.; sodium bicarbonate,  $\frac{1}{2}$ oz.; ferri sulph.-exsicc.,  $\frac{1}{2}$ oz.; pulv. carui sem.,  $\frac{1}{2}$ oz. (obtain from local chemist). (3) Change feed as far as possible; supply greenfeed (lucerne, &c.), and also bran and linseed meal.

## SUBTERRANEAN CLOVER.

(*Trifolium subterraneum*.)

[By W. J. SPAFFORD, Deputy Director of Agriculture.]

Subterranean clover has been known for a very long time in Central and Southern Europe. In those countries it is looked upon as a roadside weed, but it has been proved in South Australia to be an extremely valuable fodder plant for certain districts possessed of special natural conditions. In some types of soil it will produce more high-class fodder than will any other of the well-known fodder plants. The credit for discovering, proving, and giving publicity to this really important fodder is practically wholly due to the late Mr. A. W. Howard, of Mount Barker, South Australia, whose efforts for a period of more than 30 years in this direction are now being appreciated in all of the States of the Commonwealth, and in many other countries in the world. Mr. Howard's endeavors to popularise this fodder plant were unceasing, and throughout he acted in a most public-spirited manner, writing articles on the clover, supplying seed gratis to many parts of the world, and giving full advice on methods of handling, etc., to all who desired his help; and before his death, on March 2nd, 1930, he fortunately

**SUBTERRANEAN CLOVER**—Showing the mass of growth produced by this pasture plant when properly grown.

had the gratification of seeing the fruits of his labors, for thousands of acres in this State alone were carrying Subterranean clover, all the States of the Commonwealth were growing some of it, and requests for seed and information were being received in great numbers from almost all countries in the world having a temperate climate.

Because of its special characteristics, this clover has revolutionised the farming practices of some districts in South Australia, and has converted many farms, where difficulty has been experienced to make profits by other methods, into valuable livestock farms, with much increased land values, and capable of earning direct profits. Moreover, a really considerable area of land densely covered with scrub, which previously could not be economically cleared and cropped, has been liberated for agricultural purposes because of the ease with which Subterranean clover can be established. However looked at, the discovery of Subterranean clover as a fodder plant has been a most valuable one for Australia, and on present appearances will be recognised as such in many other countries in the near future, and the labors of Mr. A. W. Howard warrant the thanks of the country.

## DESCRIPTION OF THE PLANT.

Subterranean clover is a prostrate, soft, woolly annual, all parts of which are covered with fairly long, soft hairs. The three leaflets forming each leaf are carried on a long stalk, and each leaflet is heart-shaped and faintly toothed at the summit. The two small appendages growing at the base of the leaf stalks, although bluntly pointed, are almost oval in shape. Clusters of three or four small flowers of a creamy to pinkish color are produced on comparatively short stalks, which spring from the axils of the leaf stalks, and immediately after flowering the stalk carrying the cluster of flowers

*Reproduced from "Fodder Crops for Australia," by Leslie H. Brunning.*

**SUBTERRANEAN CLOVER**—Sod Cut from a Crop Showing Denseness of Growth and the High Proportion of Stems Made by this Plant when Grown in Suitable Conditions.

turns downwards and grows until the seed head is pushed below the surface of the soil. On penetrating the soil the parts of the flower head surrounding the fertile flowers grow sufficiently to "anchor" the seed head in the soil. Each fertile flower produces a one-seeded pod. Although an annual plant, the provision for burying most of its seed makes this clover equivalent to a perennial, and when once established it is practically permanent.

An individual plant in good conditions, and given room for development, will often completely cover the ground enclosed by a circle 6ft. in diameter, the central part of the circle, about 3ft. across, attaining up to 18in. or so in height, with the outer ring, consisting of a mass of runners, lying on the surface of the soil. Where a good stand of plants exists in fields which have been well supplied with phosphatic fertilisers, it is not unusual to have the whole land covered with a mass of luxuriant growth, 15in. to 20in. in height, the bottom 6in. or so consisting of a thick body of intermingled stalks, whilst above that is mainly leaf growth.

## CLIMATIC REQUIREMENTS.

In South Australia Subterranean clover seed germinates with the first autumn rains which are heavy enough for the purpose, and which usually occur in April or early May. The young plants make some growth during the winter period, and by the end of August will have produced a thick mass, about 4in. in height. When the warm weather of spring arrives they grow very rapidly, and remain green and continue growing until really hot weather is experienced, when they dry up. The possession of this characteristic of

making slow growth in winter, rapid growth in spring, and maturing when the hot weather arrives means that full returns from this clover can only be secured in those districts having a cool spring and long growing period, and great success will not be obtained with the crop in those districts where it is compelled to mature quickly. In South Australia most of that part of the country which receives more than 20in. of average annual rainfall has a sufficiently good climate to grow Subterranean clover well. In a general way this plant requires a temperate climate, with fairly heavy rainfall and long growing period to give full returns of fodder, and as it will withstand a fair amount of excessive wet and the ordinary cold of winter really well, *maximum results are secured in those districts receiving from 22in. to 40in. of average annual rainfall, and a growing period of about eight months between the autumn rains and the really hot, dry weather of summer*, providing always that the seed germinates before the cold weather of winter arrives.

#### SOIL REQUIREMENTS.

Subterranean clover appears to be able to accommodate itself to almost all types of soil, and, given suitable climatic conditions and sufficient phosphoric acid, will grow well in calcareous and in sour soils, in most clay soils, in all sands, and in peaty soils but *gives best returns in fertile, well-balanced loams possessed of good, natural drainage*. In this State one of the few types of soil in which the clover does not thrive well is the black, clayey soil, forming part of some of the "crab-hole" land of the South-East, but the extent of the country containing this soil type is so limited that it is not worth much consideration.

Much of the value of this clover depends on the fact that, provided phosphoric acid is supplied to the soils, it will grow extremely well on really "sour" soils, whether they be poor, whitish sands, clayey soils containing much ironstone, or really fertile loams. The poorer types of "sour" lands are usually fairly plentiful where heavy annual rainfall and temperate climate are the rule, and it is not an easy matter to produce profits from the ordinary well-known crops on such soils, but Subterranean clover flourishes in them to the exclusion of practically all other plants.

#### TIME OF SEEDING.

Where this clover has become established the *seed germinates with the autumn rains*, makes good root growth during the cold winter period, but does not make strong stem and leaf growth unless the winter is very mild and warm, and on the approach of the warm weather of the Spring season commences to make strong growth, and continues growing rapidly until maturity is reached. If the young plants have not started before the cold weather arrives, the crop does not make the luxuriant stand which follows an early germination, except when an exceptionally long-drawn-out growing season is experienced, and so, for average seasons, it is essential to seed Subterranean clover in the autumn, and, if possible, to have the land prepared beforehand. *The seed should be sown on the first autumn rain* which is sufficiently heavy to lead to the germination of the seed and, if for any reason this cannot be accomplished, it should be seeded as soon as possible, and in every case while the soil is still warm.

#### METHOD OF SEEDING.

The method of seeding Subterranean clover to ensure a good stand varies with the condition of the land, and particularly as to whether it—(a) Was recently under crop; (b) is undisturbed grass land; or (c) is covered with scrub.

*Cropped Land.*—It is much easier to establish this clover on land which is being cropped than in other locations. If it is desired to secure a full stand of clover in the first year, good soil preparation is necessary, and can be secured by ploughing some time between the Spring and Autumn, and thoroughly cultivating so that the soil is worked down to a fine tilth in time for the first seeding rain in the Autumn, say,

by the middle of April. As soon as the land is sufficiently moist to bring about a full germination, the seed should be mixed with a "carrier," and the mixture be drilled in from the manure box of the ordinary seed drill, being careful not to allow the hoes to penetrate the soil to too great a depth. It is better for the seed to be allowed to fall

Photo by E. W. Pritchard.]

**SUBTERRANEAN CLOVER**—Pieces of Stalks Showing Development from Flowers to Seed. (a) Flowers Just Opening on Very Short Flower Stalk. (b) Petals of Flowers Just Drying—Note Increased Length of Flower Stalk. (c) Petals of Flowers Fallen—Flower Stalks Grown to Place Seed Burr in Soil. (d) Seed Burr Soon After Having Reached Soil Surface. (e) Seed Burr Enlarging, Showing Developed Seed Pods.

from the drill tubes on to the roughened surface of the land and be covered by a brush harrow than for it to be drilled in too deeply. In "heavy" soils *shallow seeding is absolutely essential*, whilst in sandy soils less risk of a bad germination is taken, but even then *fin.* should be taken as the maximum depth.

Superphosphate can be used as a "carrier" with which the seed is mixed, and although there is some danger of the germination of the seed being affected injuriously by contact with superphosphate if this latter substance is "new," it appears from the results of some experiments conducted at Roseworthy Agricultural College in 1925 that Subterranean clover seed suffers less than most small agricultural seeds from lying in contact with superphosphate. It is, however, safe to use superphosphate for this purpose only when (a) the superphosphate has been stored for some time and has lost its "freshness," (b) the mixture of seed and superphosphate is made immediately before drilling, (c) the land is sufficiently moist to be in good germinating condition, or (d) the land is quite dry.

Some very good stands of clover have been secured by drilling the phosphatic fertiliser to be used with the crop into the land before seeding, and then broadcasting the seed when the soil is moist enough. Broadcasting the seed after having drilled in the fertiliser generally ensures a good, regular germination, but much more seed is required, and the quantity of seed used per acre being so small makes the even distribution of it rather difficult. If broadcasted on the surface, either by hand, with a broadcasting machine, or from the tubes of a seed drill, it should be covered by pressing it into the soil with a land roller, or, failing this, by going over the land with "brush" harrows, because most of the other farm implements tend to bury this small seed too deeply.

Where full returns are not expected the first year, it can be seeded with some other crop, and on low-priced land of light texture it is sometimes economical to treat the crop in this way. When an oat crop or a wheat crop is being seeded, a small quantity of seed can be mixed with the fertiliser being applied to the cereal. Many of these seeds will germinate and the plants will grow in the cereal crop, producing a lot of seed for the next year, and when a good germination has resulted and the stubble has not been too heavily grazed a very fair stand of clover is usually the result. A fuller germination is often secured on heavy-textured soils if the cereal is drilled in the ordinary way, then the seed broadcasted and covered by a stroke of a "brush" harrow, or by a light rolling. A stand of clover established in a crop must only be very lightly grazed the year after the crop is harvested.

In light-textured soils and in exposed situations the young Subterranean clover plants can get the protection which is so necessary to their well-being if the mixture of seed and fertiliser is drilled into a cereal stubble through a disc drill.

Extremely good first-year pastures are being secured by establishing the clover in conjunction with Wimmera Rye Grass (*Lolium subulatum*) by drilling into well-cultivated land a mixture of Superphosphate and the two kinds of seeds.

*Grass Land.*—In some circumstances fairly good stands of Subterranean clover have been secured by seeding into land without any preparatory cultivation, but this has largely been so in soils of such light texture that the hoes or discs of the seed drill will make shallow furrows when run over the ground. Even then, the drill is followed by a light harrow of some kind to make certain that the seed is covered. In this case, to give the clover plants a proper chance to compete with the plants already occupying the land, the seed should be put in before the first autumn rain, while the soil is still dry, and plenty of seed and superphosphate must be used. A really good stand cannot be expected until the second or third year after seeding when established in this way. Although some success has resulted from seeding direct into grass land, much effort and seed has been wasted by attempting this method of establishing the crop, and the experience of the last few seasons has all been in favor of loosening the surface soil in some way so that the seed can be covered at seeding time. In heavy-textured soils a couple of trips with a disc cultivator after rains in the Summer or early Autumn will

loosen the immediate surface sufficiently to enable a disc drill, followed by a "brush" harrow, to deposit the seed in the soil and cover it over. In sandy land harrows will usually do all that is necessary before the seed is drilled in.

(c) Flower Head which has Just Touched Soil Surface, Showing Commencement of Characteristic Development of Parts of Flower Head which "Anchor" the Seed Burr to the Soil. (d) Seed Head, Showing Further Growth of Flowering Parts. (e) Fully Developed Seed Burr as "Anchored" to Soil.

**Scrub Land.**—Subterranean clover can be established on scrub land in those locations suitable to the crop at a lesser cost than can any other luxuriant-growing fodder plant we have experience with in this country, but of course the original preparation for the crop differs according to the type of scrub to be handled. Where cereal crops are to

be grown during the period of establishing the clover, the land must be fairly well cleared and be properly ploughed and cultivated before drilling in the cereal. Under this system of establishment, it is common experience to find difficulty in securing a good stand of clover on these raw scrub soils unless at least two cereal crops are grown before introducing the clover seed. The clover seed can then be seeded with the third cereal crop or in the stubble of the second, as described above for seeding cropped land. If the scrub land is to be converted into Subterranean clover pasture without the help of other crops, success is dependent on leaving as much organic matter as possible on the surface of the land, and in scratching the surface in some way so that the seed can be covered. Most of the "gum" country has very little under-scrub, and clover can here be easily established by cutting off the small trees, ring-barking the larger ones, scratching the surface of the soil with a cultivator, spiked log, or such-like implement, drilling in seed and fertiliser, and "brush" harrowing. In "stringy-bark" scrub, the trees should be ringbarked, yaccas and large bushes grubbed, scrub burnt, surface of soil scratched about with a spiked log or such-like implement, which also breaks off and uproots much of the small scrub, seed and fertiliser drilled with a disc drill, or broadcasted, and the whole then "brush" harrowed. Where there is thick but stunted scrub, such as is to be found on a fair amount of our ironstone country, it should be rolled down and burnt, and either be seeded then or be allowed to stand for a year. In the former case the surface must be scratched and the seed covered after sowing, whilst if left for a year the use of a spiked log of some kind before seeding is almost essential, as it breaks off the shoots as well as scratching the surface of the land. The one-year-old shoots and scrub knocked down should on no account be burnt, but should be left to dry on the surface of the land, where they will act as a shelter for the young clover plants, which grow after seed has been drilled through a disc drill or broadcasted. Probably the best way to establish clover in *heathy scrub* is to plough the land—scrub and all—with a heavy disc plough; grow a couple of Oat crops in succession, either to be harvested or grazed by livestock, then to seed the land with clover after the second Oat crop. Once Subterranean clover has been established on scrub land it is necessary to keep down the scrub growth, and for the purpose a heavy spiked log or triangle-shaped implement specially made with railway lines to which strong spikes are fixed does the job fairly well, and at the same times does good by scoring the surface of the soil.

When establishing the crop it must be remembered that full returns will only be secured if the *seed is covered*, and when there is plenty of organic matter on the surface of the land, the first year's results are better than if the land is bare, because the young plants get protection which enables them to grow strongly from germination onwards.

#### RATE OF SEEDING.

Recent experience has firmly established the fact that if a good stand of clover is to be secured in a short while, plenty of seed must be used, and where small quantities are sown it usually takes about three years to have a full stand. To establish this clover properly in the year of seeding, even on land that has been thoroughly prepared after having carried other kinds of crops in previous years, from 6lbs. to 8lbs. of seed should be used. When the seeding is done in a cereal crop, on low-priced land, 2lbs. to 3lbs. of seed are necessary. Grass land requires 6lbs. to 8lbs. of seed drilled in the early autumn. On scrub land being directly converted into pasture, about 10lbs. of cleaned seed should be used, or else a mixture of 4lbs. or 5lbs. of cleaned seed and 15lbs. to 20lbs. of rubbishy seed as screened off at the threshing machines. This rubbishy seed consists of a little clean seed, many unthreshed clover burrs, grass seeds, and seeds of most other forage plants growing in the clover fields, and the introduction of these other plants to scrub lands where practically no edible plants exist, helps to build up the pasture more quickly than if only cleaned clover seed is sown.

## MANURING THE CROP.

As with all plants which make rapid, luxuriant growth, Subterranean clover gives best returns when liberally supplied with all the necessary plant foods, but perhaps better than most other cultivated plants it appears to have the power of extracting from almost any type of soil its requirements of other plant foods *when its needs as regards phosphoric acid are adequately met*. In all soils found in those parts of South Australia which have suitable climatic conditions for the growth of this crop, with the exception

**TOP-DRESSING SUBTERRANEAN CLOVER**—Broadcaster attached to a Motor Lorry for Top-Dressing Pasture, and for Broadcasting mixtures of Superphosphate and Subterranean Clover Seed.

of more or less white sands, the equivalent of at least 1cwt. Superphosphate (45 per cent.) should be applied per acre per year, and in all places where the soils are fertile, and the rainfall exceeds 25in. on the average, this annual dressing could be economically increased to one bag or even 2cwts. Superphosphate (45 per cent.) per acre.

The following figures, secured at Kybybolite Experimental Farm, where the average rainfall is 21.86in., are the actual grazing results from the manured Subterranean clover fields, and are the averages of the four seasons from 1925 to 1928:—

| 8. Annual dressing 45lbs. 45% super . . . .                                              | 2-71                           | 0-91                           |
| 9. Annual dressing 37lbs. 90% potash . . . .                                             | 2-38                           | 0-58                           |
| 10. No Manure . . . . .                                                                  | 1-80                           | —                              |

At present prices, the cheapest way to supply the necessary phosphatic fertiliser would be to dress the land at the rate of 1cwt. Superphosphate (45 per cent.) and 10cwt. finely ground raw Rock-phosphate (82 per cent.) per acre once every 12 years, and it would probably prove more satisfactory than applying a bag of Superphosphate (45 per cent.) per acre every year. The disadvantage of adopting this method of manuring is that the initial cost of the dressing is high, and a lot of money is locked up in the land, whereas with Superphosphate dressings it becomes an annual outlay.

It must be remembered that *it is almost impossible to grow Subterranean clover successfully unless plenty of phosphatic fertiliser is applied to the crop*, and even in the best of soils a very marked improvement to the clover crop follows every application of phosphate. All fertilisers applied to this crop should be put into the land in the autumn before the first rains have fallen, say, in March or early April.

#### USES OF THE CROP.

Subterranean clover is *mainly grown to be grazed in the green state*, but it can be converted into a very attractive and palatable hay, and is a really good "dry" feed if left to mature in the field before being grazed by livestock.

As green feed it tends to "blow" the ruminants (cattle and sheep) if they are turned on to it when wet, particularly if the animals have left a different type of fodder, but this is a recognised disadvantage of practically all leguminous fodders when green, and the danger is eliminated, or at all events lessened, by allowing the livestock

**SUBTERRANEAN CLOVER HAY**—Push Rake used to take the Clover Hay to the Hay Press.

to become accustomed to it gradually. In this stage it is a remarkably good milk producer with cows, a great fattener of cattle, sheep, and horses, and pigs do really well on it.

A good deal of care is necessary in converting the crop into hay, because it carries a very high proportion of leaf, and is at its maximum of growth before the hottest part of the summer has arrived, with the consequent danger of rain wetting the partly-cured material, so sometimes necessitating much handling. When well cured, however, the hay is much relished by all farm livestock, and they will all fatten very readily when fed with it. That this hay is of good quality is easily seen by a glance at the following table showing the analyses of three Subterranean clover hays in comparison with hays made from Lucerne and Clustered clover.

The figures representing the Starch Equivalent of each hay shows that all of the Subterranean clover hays are better than the other hays with which they are being compared:—

*Analyses and Starch Equivalence of Leguminous Hays.*

The starch equivalent for each hay has been calculated by Kellner's formula, and is a practical way of comparing foodstuffs of the same kind when to be used for fattening or maintenance purposes.

Where any considerable quantity of hay is to be made, the most economical way to do it appears to be to press it into bales in the field where grown. The crop should be cut with a mower when it begins to show signs of maturing, which is usually early in November, and should be "cocked" with a horse-rake on the same day. It should be taken to the hay-press by push-rakes as soon as cured and put straight into bales,

**SUBTERRANEAN CLOVER HAY—Pressing the Clover Hay into Bales**

which can be stacked away at once. For smaller quantities the hay should be stored in stacks. The crop should be cocked immediately it is ready, cocked within a few hours, and carted to stack as soon as it can be put away without danger of firing the stack. If water can be squeezed from the hay when a handful from the centre of the cock is tightly twisted by hand, it is not sufficiently dry to stack with safety.

If allowed to stand in the field until dry it is still greedily eaten by livestock, and despite changes in the weather and much wetting and drying it remains a most useful and estimable feed, and in this respect is much more valuable than most other of our fodder plants if left to become dry. After livestock have eaten the leaves and dry stems, they continue to do well on this crop by searching for and devouring much of the rather enormous amount of seed left at and near the surface of the ground.

Besides producing luxuriant feed for the farm livestock, Subterranean clover is a really *good soil renovator*, helping in the collection of much nitrogen by the bacteria living on its roots, and increasing the organic matter by leaves and stems dropped and trampled into the land whilst being grazed.

It is also a rather *wonderful cleaner of the soil*, for when growing well there are hardly any of the ordinary weeds found on our farmed lands which it will not choke right out. This is particularly noticeable in the case of that almost useless weed which occupied so much of the land where this clover will grow well, namely, Sorrel, which is choked out by the Subterranean clover.

#### HANDLING THE CROP.

Being possessed of prostrate stems and the power of burying its seed, Subterranean clover is enabled to *withstand much heavier grazing* than will almost any other annual fodder crop, and for that matter more than many of the perennial fodders. Nevertheless, the more care shown with the crop the greater will be the grazing results. During the winter period the crop should not be fed too close, because the more growth left on the plants at this time the greater will be the root development, and so the more rapid and more bulky the growth made when the warm weather arrives. Once the rapid growth has started livestock can be turned on to the crop, remembering that best returns can only be secured if the crop is fed off rapidly and not too close, then the livestock removed and kept off until there is sufficient growth to be a good "bite" for the animals. *Rapid feeding off and resting the pasture will give the greatest success* and can only be attained in practice by having small fields, and given this, good Subterranean clover should be capable of carrying the equivalent of 6 to 8 sheep per acre per year. At the end of the season the crop should not be fed off too close, because livestock soon learn to "stamp" for the seed, and if the land is laid bare and is then scratched by livestock, much seed will be washed from the soil, should the first autumn rain be a heavy one. Moreover, the presence of plenty of undecomposed organic matter on the surface of the land, enables clover plants which germinate in the early autumn to make much stronger growth before the winter than do plants on barer ground, and they withstand dry periods much better than those not so protected. It is in fields where plenty of clover runners have been left that good winter feed is produced the next year by Subterranean clover, whereas in those places where it is grazed right out very little is produced until well into the following spring.

If the clover fields are to receive an annual application of phosphate, rather than a heavy dressing occasionally, this should be applied in the autumn before the rains have started, say, in March or early April, either by running the drill with the hoes in the ground, or by broadcasting it on the surface and then harrowing it in.

*Clover fields should be cultivated or harrowed each year* to distribute the droppings of animals and the residues of the plants, and should be done in the autumn before sufficient rain has fallen to germinate any of the seed.

Where a rather thin stand of the clover exists, it should be only lightly grazed, leaving at the end of the season noticeable clumps of clover, and during the autumn should be harrowed two or three times to make sure that seed is dragged on to the bare patches.

If another type of crop is required from land growing Subterranean clover it can be grown without any danger of eradicating the clover, and after one such crop ample seed of the clover is left to give a full stand in the next season. Two successive crops grown on clover land will not destroy all of the seed, but when left out the clover stand is naturally rather thin, and if a full crop is required a little clover seed should be sown after the second crop has been removed.

All Clover fields should be provided with water in troughs, and livestock grazing on the clover should not have access to any other water. Wherever this practice is followed the animals make better use of the available feed and keep much healthier.

#### HARVESTING THE SEED.

No difficulty is experienced in harvesting seed which is to be used on the farm where grown. This is not so, however, for the collection and preparation of seed for market. Crops to be kept for seed are not grazed, or, if so, only lightly in the early Spring, but are allowed to grow until quite mature. When ripe the crop is raked, with a horse rake if only a limited amount of seed is required, but with hand rakes if large quantities are desired. A horse rake will collect about one-half of the seed that would be gathered

**SUTERRANEAN CLOVER HAY**—Illustration showing the high yields of Hay that can be expected from Subterranean Clover when properly grown in suitable localities.

by hand rakes from a given area. If a power thresher is available, the raked up material is passed through it, which separates the seed burrs from the stems, but if no thresher is to be used the mass is passed through a chaffcutter and the burrs winnowed from the stalks. Although some of the seeds are removed from their coverings by these methods, they constitute only a comparatively small proportion of the burrs, and the mass would not be readily saleable. Still, for one's own sowings, these burrs, if well cleaned, are nearly as good as the hulled seed, and will be fairly evenly distributed from the manure box of the drill if mixed with super., remembering that about three to four times as much unhulled seed is required as is needed if properly cleaned seed is used.

In preparing the seed for market the seed pods and burrs must be treated in a hulling machine, made specially for the treatment of this species of clover, in which all outer coverings of the seed are removed.

## PESTS OF THE CROP.

Although Subterranean clover has been grown as a fodder crop in South Australia for over 30 years now, the only pest doing noticeable damage to it is the Lucerne Flea (*Smynturus viridis*), and, although the hordes of this small insect, which appear in the early Spring, play havoc with the crop, they are only present for a short while, disappearing as the weather warms up, and the crop very quickly recovers from their attack. A grazing crop of clover affected by this pest should be rapidly fed off by livestock, and if the insects were still present when sufficient growth had been made to enable livestock to graze it, the animals should again be put on the stand. It may sometimes pay to spray an affected crop which was required for seed, using a weak solution of an arsenical spray, or soap and tobacco spray, or an oil emulsion, and if the spray was applied at night, when the insects are most active, better results would possibly be secured.

It appears that in Western Australia, the Red-legged Earth Mite (*Penthaleus destructor*) does damage to the Subterranean clover crop in certain locations, but although this pest has been known to be present in this State for some time, no complaints have been received in connection with attacks on clover crops.

## SUBTERRANEAN CLOVER IN MIXTURES.

The prostrate habit of Subterranean clover and its strong and rapid growth lead to the smothering out of most other plants growing on the same land; still, it will grow well in conjunction with any of the true grasses which start to make their Spring growth a little sooner than does the clover. The best of the grasses for this purpose are Perennial Rye Grass and Wimmera Rye Grass. Of necessity, a mixture of Perennial Rye Grass and the clover would only be attempted on really fertile soils, but on the poorer types of soil clover alone would be grown, or it could be mixed with Wimmera Rye Grass. Drained peat land or rich valley bottoms could be seeded with 4lbs. Subterranean clover and 20lbs. Perennial Rye Grass per acre if a good mixture was required, and would produce an enormous quantity of really good pasture. A mixture of 4lbs. Subterranean clover and 10lbs. of Wimmera Rye Grass seed makes a good stand of pasture, and after the first season produces much more Winter feed than can be secured from Clover alone, and the presence of the Wimmera Rye Grass does not retard the Spring growth of the Clover.

Although the Wimmera Rye Grass is only an annual, it persists when grown in conjunction with the clover, and at Kybybolite Experimental Farm some fields seeded to the mixture in 1924 still contain plenty of the grass.

## SUMMARY.

1. Subterranean clover, although known as a roadside weed in Europe for a long time, has been proved in South Australia to be a really *high-class fodder plant*, and this result is almost wholly due to the efforts of the late Mr. A. W. Howard, of Mount Barker, South Australia.
2. The power of burying its seed below the soil surface renders Subterranean clover *equivalent to a perennial*.
3. Individual plants of Subterranean clover will possibly cover the whole of a circle 6ft. in diameter, whilst a good stand of plants will cover the whole land with a dense mass of growth from 12in. to 20in. in height.
4. Subterranean clover requires a temperate climate with fairly heavy rainfall (22in. or more of average annual rainfall), and a long growing period (eight months between Autumn rains and hot, dry weather) to produce maximum returns.
5. Almost all types of soil will produce Subterranean clover *well*.
6. Much of the value of this clover depends on the fact that it will *grow well on really "sour" soils*, provided that plenty of phosphoric acid is supplied to the land.

7. The seed must be sown in time to germinate before the cold weather of winter sets in.

8. The seed can be drilled into the soil, or else be broadcasted on the surface and then worked into the land, but shallow seeding is essential. Good soil preparation is necessary if a proper stand is required in the first year, but the seed can under some circumstances be sown with another type of crop.

9. Before seeding grass land, the surface of the soil should be lightly cultivated, so that the seed can be covered with a "brush" harrow when drilled in or broadcasted on the surface.

10. Scrub land should be ploughed, cultivated, and made to carry a couple of crops of cereals before being seeded to Subterranean clover, or else the surface should be scratched with a spiked log or such-like implement, and a mixture of seed and manure be drilled or broadcasted, then "brush" harrowed.

11. It is essential that the seed be covered when establishing the crop, and the more organic matter on the surface at the time of seeding the better will be the first-year crop.

12. To secure a full stand on cropped land the year of seeding, from 6lbs. to 8lbs. of seed should be used. When sown with a cereal crop 2lbs. to 3lbs. of seed should be used. Grass land should be seeded with 6lbs. to 8lbs. of seed in the early autumn, before the first rain. Scrub land should have 10lbs. of cleaned seed, or a mixture of 4lbs. or 5lbs. of cleaned seed and 15lbs. to 20lbs. of rubbishy seed, applied per acre.

13. It is almost impossible to grow Subterranean clover well in the soils of districts with temperate climate unless plenty of phosphatic fertiliser is used, and for high returns the equivalent of from 1 bag to 2cwts. of superphosphate (45 per cent.) per acre per year should be applied. At present the application of 1cwt. of superphosphate (45 per cent.) and 10cwts. of finely-ground raw rock phosphate (82 per cent.) per acre once every twelve years is possibly the cheapest way to apply the phosphoric acid. All manuring should be done in the early autumn.

14. Subterranean clover can be used with advantage by livestock when green, as hay or as "dry" feed.

15. Analyses of Subterranean clover hays show this foodstuff to be high-class fodder, at least as good as Lucerne hay.

16. Probably the most economical way to make large quantities of hay is to cut with the mower, and, when cured, take to hay-press with a push-rake and put it straight into bales.

17. This clover is a *good soil renovator*, helping in the collection of much nitrogen, and increasing the organic matter content of the soil. It is also a *good soil cleaner*, choking out most of the ordinary farm weeds.

18. Subterranean clover should be grown in small fields, so that it can be fed off rapidly, then rested until again ready for livestock. Clover fields should be cultivated or harrowed each year in the early autumn. Thin stands should be harrowed two or three times in the early autumn to ensure that seed is spread on to the bare patches. Clover fields will allow of a crop of another kind being grown for one year without affecting the clover stand.

19. In collecting seed the crop is raked up, threshed, and then hulled in a machine made specially for the purpose.

20. Lucerne Flea is the only pest doing much damage to the Subterranean clover crops, but then only to "seed" crops, because the pastures are fed down heavily each time that they are attacked.

21. Subterranean clover will grow well in admixture with the Rye grasses on those soils suitable for these grasses.

## GREATER TRACTOR EFFICIENCY

The superiority of CROSS POWER KEROSENE is unquestioned when it is remembered that this high quality tractor fuel unfailingly provides:

Economy Quick Starting  
Full Power Less Carbon  
Low Consumption  
No Crankcase Dilution  
No Detonation Easy Idling

Used in conjunction with Cross Power Kerosene, GOLDEN SHELL OIL ensures easy and uninterrupted working, and longer life for the tractor, by successfully counteracting friction on all the moving parts in the machine.

## ROSEWORTHY AGRICULTURAL COLLEGE.

SEVENTH REPORT ON THE PERMANENT FIELD EXPERIMENTS,  
SEASONS 1904-1928.

[By W. R. BIRKS, B.Sc. (Agric.), Principal, and T. A. Cole, D.D.A., Experimentalist.]

(Continued from page 1050, July, 1930.)

14. *Crop Rotation Experiments.*

A number of rotations, introducing a variety of crops, have been tested over varying periods since the inception of the Experiments. Modifications in the plan of these tests have amounted to a gradual elimination of the more complex rotations and of all crops other than the cereals usually grown locally. Thus, at the time of the last report (1915) there were in operation, beside the standard Fallow-Wheat series, six rotations, viz., Sorghum-Wheat, Fallow-Wheat-Pasture, Fallow-Wheat-Lucerne-Lucerne-Lucerne, Pease-Wheat-Kale-Barley, Fallow-Wheat-Barley, and Fallow-Wheat-Pease-Wheat-Barley. These latter six series were closed in 1922 and after the interruption caused by the wet season of 1923, a fresh group of experiments was opened in 1924 with a re-grouping of the plots. The new series, which are still current, include the relatively well-established local rotations, viz., Fallow-Wheat-Barley, Fallow-Wheat-Oats, Fallow-Wheat-Barley-Pasture, and Fallow-Wheat-Oats-Pasture.

(a) *Fallow-Wheat.*—This system of growing wheat represents a practice commonly met with in certain districts, especially in cases in which wheat growing is the principal source of revenue and where maximum immediate returns are sought.

The pair of plots (10 and 11), in which this rotation is exemplified, moreover, have been so treated since the inception of the experiments. The results obtained from them, therefore, provide a useful basis of calculation and comparison.

In the next Table are shown the details of grain and total produce returns since 1915, together with other relevant data and mean yields. Results for 1923 and 1928 are not recorded; the former on account of the excessive wet preventing seeding and the latter on account of damage by livestock.

TABLE XL.—*Showing Harvest Returns from Wheat Grown Continuously after Bare Fallow, with 1cwt. Superphosphate per Acre, 1905-27.*

| 1920 .....                 | 1                          | 10 | 98 | 16                 | 5    | 155                                 | 61½                       |
| 1921 .....                 | 1                          | 3  | 66 | 12                 | 23   | 153                                 | 57                        |
| 1922 .....                 | 1                          | 6  | 93 | 15                 | 5    | 139                                 | 63                        |
| 1924 .....                 | 1                          | 2  | 53 | 12                 | 30   | 141                                 | 63                        |
| 1925 .....                 | 2                          | 5  | 46 | 24                 | 30   | 148                                 | 63                        |
| 1926 .....                 | 1                          | 12 | 36 | 14                 | 29   | 190                                 | 62½                       |
| 1927 .....                 | 0                          | 18 | 97 | 10                 | 52   | 134                                 | 58                        |
| Means for 22 seasons ..... | 1                          | 12 | 56 | 18                 | 28   | 142                                 | 62                        |
| Hay equivalent .....       | 1                          | 19 | 71 | —                  | —    | —                                   | —                         |

This gives a mean gross return of £4 3s. 1d. per acre for grain and £4 19s. 1d. for hay returns. In order to arrive at a net value for these returns, for the purpose of comparison, arbitrary figures, representing items of cost of production, have been

adopted as follows:—Rental value of the land, 10s. per acre per annum; cost of fallowing, seeding, and harvesting operations, including costs of seed and manure, &c., £2 10s. per acre. Making deductions for two years' rental, plus cost of field operations, we thus arrive at the mean net figures of 13s. 1d. per acre of crop for grain and £1 9s. 1d. per acre for hay returns. Spreading these returns over the whole area occupied by the rotation we get the mean net returns per acre of 6s. 6d. and 14s. 6d. for grain and hay respectively.

These figures emphasise the more remunerative returns to be expected from hay growing, where hay can readily be disposed of, than from wheat marketed as grain. The marked difference in the case of these tests is associated, no doubt, with the high proportion of straw to grain recorded in the above Table. The mean grain yield represents only 30 per cent. of the total produce, a relatively low proportion which in its turn is a result, no doubt, of our severe Spring and early Summer conditions, which not infrequently force a more or less premature ripening and shrivelling of the grain.

To the figures representing net crop returns must be added the value of sheep grazing provided by the fallow, the stubbles, and Winter growths. The first of these items is assumed, from previously recorded results, to be represented by the equivalent of .25 sheep per acre for a year: the other two (stubble and Winter grazings) have been recorded in the plots and details since 1916, together with mean results since 1907, are shown in the next Table.

TABLE XLI.—*Showing the Grazing Capacity of Land Alternately Fallowed and Sown to Wheat, Expressed as Sheep per Acre for a Year, 1907-28.*

| Year.                      | Fallow<br>Grazing. | Stubble<br>Grazing. | Winter<br>Grazing. | Total<br>Grazing. |
|----------------------------|--------------------|---------------------|--------------------|-------------------|
| 1916 .....                 | .25                | .89                 | .11                | 1.25              |
| 1917 .....                 | .25                | .36                 | .20                | .81               |
| 1918 .....                 | .25                | .42                 | .00                | .67               |
| 1919 .....                 | .25                | .33                 | .00                | .58               |
| 1920 .....                 | .25                | .54                 | .30                | 1.09              |
| 1921 .....                 | .25                | .64                 | .31                | 1.20              |
| 1922 .....                 | .25                | .74                 | .37                | 1.36              |
| 1923 .....                 | .25                | .57                 | .00                | .82               |
| 1924 .....                 | .25                | .00                 | .37                | .62               |
| 1925 .....                 | .25                | .40                 | .00                | .65               |
| 1926 .....                 | .25                | .64                 | .22                | 1.11              |
| 1927 .....                 | .25                | .64                 | .00                | .89               |
| 1928 .....                 | .25                | .33                 | .00                | .58               |
| Means for 22 seasons ..... | .25                | .48                 | .23                | .96               |

At the adopted value for sheep grazing (12s. 6d. per sheep per annum), this gives a mean value for total grazing of 12s. for the whole area covered by the test, or 6s. per acre per annum.

Adding this value to the net returns from cropping, we arrive at the figures 12s. 6d. and £1 0s. 6d. (for wheat farming and hay growing respectively) representing the probable net returns per acre per annum from a farm worked wholly on the fallow-wheat rotation. The figures cannot be taken as representing the actual financial results of farming operations in practice, as certain overhead and managerial expenses have not been taken into account: they do, however, provide a basis of comparison for the results of other rotational tests which are calculated in a similar way.

(b) *Sorghum-Wheat*.—This rotation was in force in a pair of plots (12 and 13), adjoining those considered in the foregoing paragraph, from 1905 to 1922. The object of this test is to compare the value of the extra grazing provided by the sorghum, with the value of the wheat or hay sacrificed in the succeeding crop as a result, no doubt, mainly of the depletion of soil moisture during the growing period of the sorghum.

In the next Table the results from the Sorghum-Wheat rotation are shown in comparison with those of the Fallow-Wheat rotation for the corresponding period. Total grazing returns are included and the differences shown, generally to the credit of the

Sorghum-Wheat rotation, are due almost entirely to the difference between the mean fallow grazing figure (.25 sheep for a year) and the extra grazing provided by the sorghum during the Summer and early Autumn preceding wheat seeding.

TABLE XLII.—Showing Crop Returns and Total Grazing Provided in Fallow-Wheat and Sorghum-Wheat Rotations, 1906-1922.

| Year.                | Fallow-Wheat Rotation. |    |    |                 |                               | Sorghum-Wheat Rotation. |    |    |                 |                               |

| 1922                 | 1                      | 6  | 93 | 15 6            | 1.36                          | 1                       | 6  | 80 | 14 50           | 1.90                          |
| Means for 17 seasons | 1                      | 11 | 42 | 17 58           | .97                           | 1                       | 8  | 16 | 14 57           | 1.43                          |
| Hay equivalent       | 1                      | 18 | 29 | —               | —                             | 1                       | 14 | 36 | —               | —                             |

From these figures it appears that the introduction of sorghum as a fallow crop has been responsible for an increase in grazing value equivalent to approximately  $\frac{1}{4}$  sheep per acre over the whole area and also for a loss in the wheat crop returns of 3cwt. 105lbs. of hay, or 3bush. 1lb. of grain. In order to appraise the net result more clearly, a statement of receipts and expenditure is set out in the next Table. The arbitrary cost figures previously referred to are embodied in this, and in addition 8s. per acre is included to represent the cost of sorghum seed (7lbs.) and the manure sown with it ( $\frac{1}{2}$ cwt. bonedust). It is assumed that the costs of preparing the land in Winter and early Spring for sorghum seeding and of the intercultivation of this crop in Summer, are equivalent to those incurred in the breaking up and Summer working of the fallow.

TABLE XLIII.—Comparing Gross and Net Returns from Wheat and Wheaten Hay Crops Grown under Fallow-Wheat and Sorghum-Wheat Rotations, 1906-1922.

|                                                             | Fallow-Wheat. |         | Sorghum-Wheat. |         |
|-------------------------------------------------------------|---------------|---------|----------------|---------|
|                                                             | Hay.          | Grain.  | Hay.           | Grain.  |
| Receipts—                                                   | £ s. d.       | £ s. d. | £ s. d.        | £ s. d. |
| Crop                                                        | 4 15 8        | 4 0 10  | 4 5 10         | 3 7 3   |
| Grazing                                                     | 0 12 2        | 0 12 2  | 0 17 11        | 0 17 11 |
| Total receipts per acre for two years                       | 5 7 10        | 4 13 0  | 5 2 9          | 4 5 2   |
| Expenditure—                                                |               |         |                |         |
| Rent at 10s. per acre per annum                             | 1 0 0         | 1 0 0   | 1 0 0          | 1 0 0   |
| Cost of production                                          | 2 10 0        | 2 10 0  | 2 18 0         | 2 18 0  |
| Total expenditure per acre for two years                    | 3 10 0        | 3 10 0  | 3 18 0         | 3 18 0  |
| Balance of receipts over expenditure per acre for two years | 1 17 10       | 1 3 0   | 1 4 9          | 0 7 2   |
| Balance of receipts over expenditure per acre per annum     | 0 18 11       | 0 11 6  | 0 12 5         | 0 3 7   |

Thus the practice of allowing a sorghum crop, instead of a bare fallow, to precede wheat, results in a relative loss of 6s. 6d. per acre per annum in the case of hay returns and 7s. 11d. per acre per annum in net grain returns. It is to be expected that the loss in grain returns is proportionately greater than that in hay yields: another effect, no doubt, of the depletion of moisture reserves in the soil which might be expected to have a more marked effect upon the ability of a crop to fill the grain than upon straw growth.

In the earlier reports on this test, a definite falling-off in the quality of wheat grown after sorghum, as indicated by bushel weight, was recorded. At present, however, this effect is not indicated by the mean of the recorded figures; the average bushel weight of the wheat from the Sorghum-Wheat plots is identical with that of the wheat from the Fallow-Wheat plots, namely, 62lbs. (*vide* Table XL.).

In 1913 a subdivision of the Sorghum-Wheat plots was made in order to test, on half of each plot, the effect of dressing the land with 14 tons of farmyard manure before seeding each sorghum crop. The figures recorded in Tables XLII. and XLIII., as representing returns in the Sorghum-Wheat rotation, were, therefore, obtained from plots of about 1 acre only for the period 1914-1922. These figures are shown again in the next Table, along with results recorded in the half-plots receiving the farmyard manure as well as the mineral manures used in the original rotation.

TABLE XLIV.—*Showing Comparative Results from Two Sorghum-Wheat Rotations, in One of which Farmyard Manure at the Rate of 14 Tons per Acre was Applied to the Sorghum, 1914-1922.*

| Year.                  | Sorghum-Wheat with Farmyard Manure. |    |                         |    |                                  | Sorghum-Wheat with Mineral Manures only. |    |                         |    |                                  |    |      |   |    |   |   |    |   |

|                        | 2                                   | 19 | 8                       | 4  | 4                                | 6                                        | 1  | 1                       | 3  | 3                                | 4  | 8    | 3 | 17 | 1 | 0 | 18 | 9 |

The addition of farmyard manure, has thus had the effect of reducing the value of the wheat yield (by 5s. per acre), but has increased the hay and grazing returns by amounts, expressed in money values, of 7s. 5d. and 2s. 6d. respectively, making a total increase of 4s. 11d. per acre in favor of farmyard manure plots. The cost of application of this manure, however, as is usually the case, quite overshadows the value of any immediate returns which it might produce, and the net result is that the rotation in which mineral manures only are used shows an annual profit of 8s. 11d. per acre for the whole area (taking the hay return figures), and that in which farmyard manure is used shows an annual loss of £1 1s. 2d. per acre. The corresponding figures for grain returns are 2s. 9d. per acre per annum profit and £1 13s. 7d. loss.

(c) *Fallow-Wheat-Pasture*.—This rotation, which may be regarded as a standard one in South Australian farming practice, has been in force since 1905, but fencing was not completed until 1906, so that recorded grazing results for the first season are not available. The series was closed, along with others, in 1922, and there are thus the results of 17 seasons' work to be recorded.

In the "grazing" year in this rotation a light seeding of rape (4lbs. per acre) was applied to each wheat stubble, following a shallow working, in order to ensure an abundance of succulent feed in the event of satisfactory Autumn rains occurring. The cost of this seeding is computed at 5s. per acre. A corresponding addition to the normal working expenses is made in the calculations below. The wheat received 1cwt. superphosphate per acre, so that results are comparable with those of the Fallow-Wheat rotation already recorded.

In the next Table are shown the details of crop returns and total grazing provided by the whole area each year since 1915, together with mean results and values.

TABLE XLV.—*Showing Crop Returns and Total Grazing Provided by Land coming under Wheat Once in Three Years and Dressed Regularly with 1cwt. Superphosphate, 1906-1922.*

Deducting from the crop values the costs of working (£2 10s., plus 5s.), and adding the remainder to the grazing value, we get £4 0s. 1d. and £3 1s. 5d. per acre as the total net returns for three years from hay and grain returns respectively. Three years' rent (30s.) is to be deducted from each of these totals, and the remainder divided by 3 gives the net return per acre per annum for the whole area covered by the rotation. This figure for hay returns is 16s. 8d. and for grain 10s. 6d. Comparing these with the corresponding figures for the Fallow-Wheat rotation (Table XLIII., 18s. 11d. and 11s. 6d. respectively), it is seen that there is a difference of 2s. 3d. per acre per annum in the case of hay returns and 1s. per acre per annum in that of grain yield. From the results of this test, then, it appears that the introduction of a year of pasture into the fallow-wheat rotation involves a small loss in net returns per acre. This loss is, however, in practice amply offset by the advantages of diversification of farming which the extra pasture area allows and by the enrichment of the soil which naturally results from the depasturing of livestock upon it. It is to be noted that, of the mean total grazing indicated by the figure 2.92 in the above Table, 1.74, or approximately two-thirds of the total, is provided in the pasture year of the rotation.

(d) *Fallow-Wheat-Barley*.—This test represents an attempt to secure a greater direct monetary return from cropping than is to be expected from either of the rotations already considered. The plots on which it was carried out from 1911 to 1922 are Nos. 38, 39, and 40. These are situated some 15 chains from the nearest of those dealt with in the foregoing paragraphs of this section, viz., the Fallow-Wheat-Pasture group. They were not fenced and hence detailed grazing figures are not available; moreover, in this series both the wheat and the barley received 2cwt. superphosphate per acre at each seeding, and the results are therefore not comparable with those of the Fallow-Wheat-Pasture series referred to above. There was, however, adjoining the latter series another which was treated similarly, except that the wheat received 2cwt. superphosphate per acre at each seeding. The results from this series have, therefore, been compiled as a basis of comparison for the Fallow-Wheat-Barley rotation. In order to arrive at an estimate of the grazing returns from this series the following figures have been taken: for the fallow grazing, the usual .25 sheep per acre; for the grazing on the wheat stubble, the same figure as is recorded in the control series, Fallow-Wheat-Pasture; for the grazing on the barley stubble, the same figure as for the wheat stubble (which is in all probability an under-estimate); and for the

Autumn grazing prior to fallowing, again the same figure as in the other series. This amounts to a substitution of a stubble grazing in the one for the full year's pasture in the other series, and provides a grazing figure for the Fallow-Wheat-Barley rotation which is lower than that of the control series, and although an estimate only, is probably well on the safe side.

A summary of the results from the two series of plots is set out in the next Table.

TABLE XLVI.—*Showing Comparative Crop and Grazing Returns from the Two Rotations Fallow-Wheat-Pasture and Fallow-Wheat-Barley, 1911-1922.*

It will be seen that the rotation including barley shows a loss in grazing value of approximately one sheep per acre for a year and this is offset by the whole value of the barley crop. The wheat returns in this rotation are better by 2½ bush. of grain, or almost 3 cwt. of hay, per acre, but this cannot be claimed as a result of any beneficial effect exerted by the barley. The difference is probably due to experimental error arising from the relatively wide separation of the groups of plots. In any case, however, the increase in net returns, which are shown below to be apparently due to the introduction of the barley into this three-course rotation, is far greater than could be accounted for by this extra yield of wheat.

In arriving at the respective net results in these tests the same deductions as before have been made for costs, viz., £2 10s. per acre for normal wheat production, 10s. per acre per annum for rent, 5s. per acre for rape seeding in the pasture year, £1 15s. per acre for the normal cost of barley growing. In addition, 4s. 6d. per acre has been added to the cost of each seeding to represent the cost of extra superphosphate as compared with the 1 cwt. provided for in normal costs. After making a calculation similar to that shown in Table XLIII, the following net returns are shown:—For the Fallow-Wheat-Pasture rotation 13s. 5d. and 9s. 1d. per acre per annum when the wheat crop is disposed of as hay and grain respectively; and for the Fallow-Wheat-Barley rotation the corresponding figures are 18s. 11d. and 15s. 9d.

It would appear, then, that the introduction of barley has been responsible for a substantial increase in net annual returns; an increase of about 6s. per acre per annum.

It is to be noted that the period covered by this test includes a bigger proportion of lean years than occurred in the periods of other rotational experiments already dealt with and mean crop returns are correspondingly lower. Nevertheless, the figures representing net annual returns per acre for the Fallow-Wheat-Barley rotation (18s. 11d. and 15s. 9d.) compare favorably with the corresponding figures for the Fallow-Wheat rotation (18s. 11d. and 11s. 6d.), and the association of barley with wheat in this way may be said to show better returns than either of the other systems of farming dealt with so far.

(To be continued.)

## THE IDENTIFICATION OF *PHALARIS TUBEROSA* (syn. *BULBOSA*) AND *PHALARIS MINOR* IN SEED SAMPLES AND IN THE FIELD.

[By H. C. TRUMBLE, M. Agr. Sc., Waite Agricultural Research Institute,  
University of Adelaide.]

### IMPORTANCE OF PHALARIS GRASSES TO SOUTH AUSTRALIA.

Investigations at the Waite Institute have indicated that *Phalaris tuberosa* (Toowoomba Canary Grass) is a promising pasture grass for climatic conditions resembling those of Adelaide, and for the more favored areas of the State. It is distinguished from other species of *Phalaris* by its perennial nature, underground rootstock, bulbous bases to the mature tillers, and a long, tapering seed-head. A free-tillering, semi-subterranean habit enables it to withstand close grazing, and if stocked heavily the grass forms a close turf.

For many years this species has been known as *Phalaris bulbosa* L. Allan and Zotov, however, have recently presented evidence<sup>1</sup> to show that the correct name of the grass is *Phalaris tuberosa* L., and that grasses in different parts of the world known respectively as *P. nodosa*, *P. stenoptera*, and *P. bulbosa* are actually *P. tuberosa*. Bews<sup>2</sup> in his "World's Grasses" uses the name *Phalaris tuberosa* (syn. *bulbosa*). The name *P. commutata* has also been frequently used in Australia, but quite erroneously, there being no grass of this name. It is evident, as Allan and Zotov say, that<sup>3</sup> to avoid further confusion the names "*commutata*," "*bulbosa*," "*stenoptera*," and "*nodosa*" should be dropped altogether, and, pending further investigation of the group, the name *Phalaris tuberosa* be used exclusively for the perennial bulbous grass commonly known as Toowoomba Canary Grass.

The particular reasons for the value of this grass over much of the winter rainfall zone of Australia are firstly its drought-resistance, and secondly its ability to produce feed rapidly with the first seasonal rains. The grass is normally dormant during summer, but produces feed after thunderstorms. The perennial root system with long, fibrous rootlets is protected by a tough, woolly covering and has been traced through subsoil clay at the Waite Institute to a depth of 42in.

*Phalaris tuberosa* has been grown in South Australia since 1906, when Mr. A. Canning, of Murraytown, exhibited a sheaf of the grass at the Adelaide Royal Agricultural Show. Records are available of its having since been grown successfully at Geranium, Jamestown, Georgetown, Saddleworth, Kingscote, Port Elliot, Naracoorte, Mount Remarkable, Willunga, Williamstown, Gumeracha, and Meadows on annual rainfalls varying from 17in. to 36in. Except at Williamstown, however, where more than 100 acres have been established, the grass has been sown only on a small scale. Nevertheless, at most of the centres above mentioned, it is still to be found persisting, more than 20 years after the original sowings.

*Phalaris minor* is an annual with no underground rootstock nor bulbous bases to the tillers, but it resembles *Phalaris tuberosa* in leaf characters, and to a considerable degree in panicle and seed characters as well. Like Wimmera Rye Grass and the cereals, it produces little feed until some weeks after the seeds have germinated in autumn or winter; in addition the mature plants will not respond to rain after the seed has ripened

1. New Zealand Journ. of Agric., XL., No. 4 (April, 1930), pp. 256-264.

2. "The World's Grasses." J. W. Bews, 1929.

in early summer. *Phalaris minor* is comparable in vigor under Adelaide conditions to Wimmera Rye Grass, but is a temporary element only, and distinctly inferior as a pasture plant to the perennial *Phalaris tuberosa*. The annual species could, however, be used as an alternative to Wimmera Rye Grass in this State.

The two other *Phalaris* grasses naturally occurring in South Australia, namely, *Phalaris canariensis* and *Phalaris paradoxa*, are found but rarely in pastures. *Phalaris canariensis* was grown in earlier years as a grain crop for bird seed.

#### PRESENCE OF PHALARIS MINOR SEED IN PHALARIS TUBEROSA SAMPLES.

As early as 1909, Mr. G. T. Griggs, of Meadows,<sup>3</sup> reported that he had obtained success with *Phalaris tuberosa* by root planting, but that on purchasing seed had found that the resulting plants were all *Phalaris minor*. This has also been the experience of others, and is probably one reason why the grass has not increased in popularity in South Australia. Allan and Zotov<sup>4</sup> note that *Phalaris minor* has occasionally been grown as a crop and the seed sold under the misapprehension that it was Toowoomba Canary Grass, in both New Zealand and Australia, and quote Kennedy,<sup>5</sup> who, in 1917, stated:—"That much, if not all, of the seed of *Phalaris* now on the markets of New Zealand and Australia is hopelessly mixed seems to be certain."

At the Waite Institute difficulty has been experienced in obtaining pure *Phalaris tuberosa* seed for experimental purposes, and this, in addition to the unsatisfactory nature of the general position, has led to a study of the "seed" and seedling characters of the two species, with a view to obtaining a ready and constant means of identification.

During the last 15 months, 43 samples of seed labelled as *Phalaris bulbosa* have been received from leading seedsmen in Australia and from private individuals interested in the grass. In addition, more than a hundred samples of *Phalaris tuberosa* have been collected by the writer from plants growing naturally in different parts of the State. Of the 43 samples first mentioned, 29 were found to be pure *Phalaris tuberosa*, 10 to be pure *Phalaris minor*, three to be mixtures of the two species, and one a different species. Of 20 samples obtained from seed merchants, only 12 were pure *Phalaris tuberosa*, four were pure *Phalaris minor*, three were mixtures of the two species, and one was actually an unrelated grass, *Poa bulbosa*.

#### BOTANICAL FEATURES OF PHALARIS TUBEROSA AND PHALARIS MINOR "SEEDS."\*

The botanical features of *Phalaris tuberosa* and *Phalaris minor* have recently been described by Allan and Zotov<sup>6</sup>, who also give an account of the origin of *Phalaris tuberosa* in Australia<sup>7</sup>. Whereas the descriptions given in the case of these species apply to samples typical of each species, an examination of the material collected by the Waite Institute has shown that there is a whole series of "seed" types ranging from typical *Phalaris tuberosa* down to typical *Phalaris minor*, with intermediate types occurring in both species. Although typical "seeds" of each grass differ fairly definitely in shape, color, pubescence, and nature of the glume appendages, the "seed" characters of the two species, and of *Phalaris tuberosa* in particular, vary so greatly that in some cases it is impossible to identify the species with certainty from the "seed" alone.

\* The "seed" characters described are, of course, those of the fertile glumes, or husks, surrounding the actual grain.

The main "seed" characters as described by Allan and Zotov are listed below. The most constant and characteristic features as borne out by South Australian collections are presented in heavier type.

|                                    | <i>Phalaris tuberosa.</i>                                | <i>Phalaris minor.</i>                                   |
|------------------------------------|----------------------------------------------------------|----------------------------------------------------------|
| 1. COLOR .....                     | Pale to dark-brown shining                               | Dark brownish grey                                       |
| 2. VENATION .....                  | Finely striate with 5 distinct nerves                    | Indistinct                                               |
| 3. PUBESCENCE .....                | Sparse or rather dense, especially in upper two-thirds   | Dense save for distinct bald patch in lower third        |
| 4. SHAPE .....                     | Narrow, ovate, lanceolate, gradually tapering to a point | Broadly ovate, lanceolate, abruptly narrowing to a point |
| 5. LENGTH .....                    | 3.25 mm.                                                 | 2.75 mm.                                                 |
| 6. BREADTH .....                   | 1.25 mm.                                                 | 1.25 mm.                                                 |
| 7. APPENDAGE TO 1ST STERILE FLORET | Minute up to 0.75 mm. long                               | Absent                                                   |
| 8. APPENDAGE TO 2ND STERILE FLORET | Up to 1.75 mm. long                                      | Up to 1 mm. long, rather more hairy                      |

In addition, the "seeds" of *Phalaris minor* tend to be rather more compressed, giving them a slightly flatter appearance than those of the perennial species.

#### UNRELIABILITY OF "SEED" CHARACTERS.

Color appears to be the least constant of the above characters so far as Australian samples are concerned, and is largely dependent on stage of maturity. It is also probably affected to some extent by the environmental conditions obtaining during the ripening period.

In most other characters, *Phalaris minor* "seeds" usually conform closely to the descriptions given above for this species, and may readily be identified. The occurrence of some samples, however, with pale "seeds," not highly pubescent, and tapering quite as gradually as some forms of *Phalaris tuberosa*, renders the identification of *Phalaris minor* not a positive one. Furthermore, *Phalaris tuberosa* is variable in most of the characters described. In some samples the veins are indistinct as in *Phalaris minor*; the shape, and degree of pubescence are particularly variable, whereas the appendage to the first sterile floret is sometimes considerably reduced, and may be altogether absent, particularly in the case of "seeds" from machine-dressed samples. The result of the realisation that the "seed" types of each species definitely overlap is that one is reluctant to pronounce a verdict on a supposedly *Phalaris tuberosa* sample from the evidence of "seed" characters alone.

The absence of the appendage to the first sterile floret in certain "seeds" from plants that otherwise conform to *P. tuberosa* corroborates the specimens sent to Professor Hackel, in 1908<sup>8</sup>, and tends to contradict the theory put forward by Kennedy that these were composed of the vegetative portions of *P. tuberosa* and "seeds" of *P. minor*.

Fig. 1 indicates the variability found in each species. The top row of seven "seeds" depicts seven distinct types of *Phalaris tuberosa* taken from samples which produced perennial plants only, whereas the bottom row is composed of "seeds" from samples which produced only *Phalaris minor*. In the case of each species the most typical specimens are to the left, and the least typical on the right.

8. Allan and Zotov; *loc. cit.*

The details as to the origin of the seeds in Fig. 1 are as follows:—

*Phalaris tuberosa* (top row). Nos. 1, 4, and 7 from *Phalaris tuberosa* plants growing at the Waite Institute. Nos. 2, 3, 5, and 6 from commercial samples which produced *Phalaris tuberosa* plants only.

*Phalaris minor* (bottom row). Nos. 1, 4, and 7 from *Phalaris minor* plants growing at the Waite Institute. Nos. 2, 3, 5, and 6 from commercial samples sold as *Phalaris bulbosa*, but producing *Phalaris minor* plants.

Fig. 1.—“Seeds” of *Phalaris tuberosa* (top) and *Phalaris minor* (bottom).

#### CHARACTERS OF GERMINATING SEEDS.

The unreliability of “seed” characters being thus apparent, germinating seeds and young seedlings were studied, with the result that a simple and readily determinable difference was found in the germinating roots of the two species.

In the case of *Phalaris minor* the tip of the radicle or young root is colored a bright pink (Fig. 2), whereas in *Phalaris tuberosa* it is colorless or slightly yellowish. By placing the seeds on moist filter paper at 20° C. the character may be obtained within four days. Of 45 samples of pure *Phalaris tuberosa* tested in this way, no pink tips have been found. This applies also to *P. arundinacea*, *P. canariensis*, *P. angusta*, *P. brachystachys*, *P. caroliniana*, *P. coerulescens*, *P. lemmonii*, and to *P. stenophylla*, which, although perennial and said to be superior in N.S.W. to *P. tuberosa*, has seeds resembling *P. minor* in shape. Of 10 *Phalaris minor* samples tested, all seeds showed the pink-tipped character. One commercial sample which produced pure stands of *Phalaris minor* in the field, showed some white-tipped radicles among a majority of pink tips, and for a time caused doubt to be thrown on the constancy of the difference. The resulting seedlings have since been shown, however, to be of two kinds, typical respectively of the two species, and it has been assumed that in the heavy rate of seeding adopted, the perennial plants were eliminated as a result of competition from the more rapidly growing annual, which ultimately obtained complete possession of the plot. This sample is being further investigated.

Pink radicle tips have been found in European, American, and New Zealand samples, as well as those of Australian origin. On the basis of data so far available it would seem that some indication of the presence or absence of *Phalaris minor* may be obtained from the appearance of the seeds as described by Allan and Zotov, and emphasised in this paper. The occurrence of pink-tipped radicles in the germinating seeds of the sample appears, however, to be a more reliable guide, particularly in border line cases, and samples in which pink-tipped radicles occur in quantity on germination should

certainly not be sown where a *Phalaris tuberosa* sward is desired. The pink-tip character also enables the percentage of viable seeds of each species in a sample to be determined with accuracy. The coloration in the case of *Phalaris minor* appears to persist, and has been noted on the roots of plants several months after germination.

Fig. 2.—Germinating Seeds of *Phalaris minor*.

#### SEEDLING, VEGETATIVE, AND MATURE PLANT CHARACTERS.

The seedlings of the two species show little difference. *Phalaris minor* tends to be rather more vigorous in growth from seed and more papery in texture. The germination of both species is active. The leaves of *Phalaris tuberosa* tend to become slightly stiffer and more fibrous than those of the annual species. Microscopic sections of young leaves indicate that there is little difference in vascular structure. *Phalaris tuberosa* tends to produce fibre at rather an earlier stage and to produce epidermal hair cells in more abundance, but the differences are not sufficiently great to be made use of. As active tillering commences, differences become pronounced, and it is possible to identify the species with certainty. The tillers of *Phalaris tuberosa* arise from below the soil surface, growing at a low angle for some distance through the soil before becoming visible. On emergence the tillers assume a stiff appearance, and the crown of the plant is seen to be subterranean. On the other hand, the tillers of *Phalaris minor* arise from above soil level and assume a more succulent, drooping appearance. The young tillers of either species, on being cut near the base, exude sap of a reddish color, and this is a positive test for those species of the genus found growing in South Australia.

*Phalaris minor* is considerably earlier than the perennial species, the dates of flowering and maturity at Adelaide in 1929 being as follows:—

|                                   | Flowering. | Maturity.   |
|-----------------------------------|------------|-------------|
| <i>Phalaris minor</i> .. . . .    | October 4  | November 6  |
| <i>Phalaris tuberosa</i> .. . . . | November 8 | December 18 |

The panicle of *Phalaris minor* is cylindrical in shape and about four times as long as it is broad. The panicle of *Phalaris tuberosa* is typically tapering and about six to eight times as long as it is broad. The shape and length of the panicle varie considerably in *Phalaris tuberosa*, however, specimens having been found with panicle

Fig. 3.—Seedlings of *Phalaris tuberosa* (left) and *Phalaris minor* (right).

similar to those of a typical *Phalaris minor* head. A character of the mature seed head which has so far proved reliable is the nature of the wing to the outer sterile glumes, as described by Allan and Zotov<sup>10</sup>; abruptly pointed in *Phalaris tuberosa*, and incurving sharply pointed in *Phalaris minor*.

10. *Loc. cit.*

PRESENT RESTRICTIONS TO THE USE OF *PHALARIS TUBEROSA* IN SOUTH AUSTRALIA.

The unreliability of commercial samples of *Phalaris tuberosa* has been a serious drawback in the past, and it is hoped that the data here presented will be of value in overcoming this difficulty. It is encouraging to learn that seeds merchants are anxious to eliminate *Phalaris minor* from their samples.

The present high price of the seed, which is approximately 6s. per lb., considerably restricts the use of the grass by farmers, and is probably governed by the demand and by the low yields of seed normally obtained per acre.

Selection is being employed at the Waite Institute as a means of isolating productive and persistent strains of superior seed-yielding ability. The preliminary work so far accomplished indicates considerable variability within the species and ample scope for improvement by this means.

## STATE OF SOUTH AUSTRALIA

## ACREAGE OF CROPS, SEASON 1930-31.

The Government Statist reports having completed an estimate of the probable acreage, either sown or intended to be sown with cereals, for the season 1930-31. This estimate is based on returns received some time ago from farmers in each agricultural hundred of the State. It should be understood that the estimate represents the areas farmers anticipated sowing. The serious lack of early seasonal rains would have prevented many farmers actually sowing to the extent anticipated, and in some districts resowing will be necessary. It is thought, however, that the bountiful general rains of early July may now so expedite sowing that the estimate based on early reports may prove to be reasonably accurate.

Following the usual practice, further reports will be obtained after all sowing is completed, when the whole of the figures will be reviewed for a more confident estimate to be issued in September.

*Estimated Wheat Acreage.*

| Division.           | Actual,<br>1930. | Estimated,<br>1930-31. | Increase. |
|---------------------|------------------|------------------------|-----------|
|                     | Acres.           | Acres.                 | Acres.    |
| Central .....       | 639,010          | 691,000                | 51,990    |
| Lower North .....   | 894,623          | 918,000                | 23,377    |
| Upper North .....   | 281,523          | 326,000                | 44,477    |
| South-Eastern ..... | 50,356           | 68,000                 | 17,644    |
| Western .....       | 1,088,053        | 1,273,000              | 184,947   |
| Murray Mallee ..... | 1,033,745        | 1,168,000              | 134,255   |
| Total State .....   | 3,987,310        | 4,444,000              | 456,690   |

*Barley*.—Actual, 1929-30, 320,123 acres; estimated, 1930-31, 280,000 acres.

*Oats*.—Actual, 1929-30, 520,428 acres; estimated, 1930-31, 512,000 acres.

*Expansion of Last Five Seasons*.—The total area sown for all purposes with wheat, barley, and oats has increased from 3,410,213 acres in 1925-26 to 4,827,861 acres for 1929-30—a four years' increase of 1,417,648 acres, with a further increase of 408,000 acres if the estimated intended sowing of 5,236,000 acres for 1930-31 is realised.

*Prospects*.—Notwithstanding the serious shortage of rain to the end of June, statistics indicate that, with the bountiful general rains of this month, followed up by good spring rains to November, the State may yet reap a reasonable harvest.

*Five Year's Clearing of New Land*.—During the last five years 886,381 acres have been cleared in the Western Division, 225,782 during 1929-30, and 725,301 acres in the Murray Mallee Division, 138,233 acres during 1929-30. The total for the whole State is 1,726,258, and 392,168 acres for year 1929-30.

# LACK OF ARSENIC TO BLAME!

ON THE QUESTION OF INEFFICIENT SHEEP DIPS—

Many dips on the market contain a low percentage of arsenic, yet they are called ARSENICAL DIPS, but are inefficient.

## YOUNG'S SHEEP DIP

(POWDER)

complies with the requirements of the Stock and Brands Department for South Australia, and contains considerably more than the percentage of Arsenic stipulated under the Act, and will KILL TICK and LICE, and resist the Blowfly attack.

Try also YOUNG'S BRACKISH WATER SHEEP DIP. Mixes readily with Fresh or Brackish Water.

FROM ALL STORES.

## BOOBOROWIE EXPERIMENTAL FARM HARVEST REPORT, 1929-1930.

[By R. C. SCOTT, Supervisor of Experimental Work, and E. A. BRISTOW, Manager.]

The Booborowie Farm is situated about 120 miles north of Adelaide, and 12 miles west of Hallett. The total area is 1,484 acres, of which 1,186 acres surrounds the old North Booborowie Station homestead, and the remainder, 298 acres, is situated some two miles distant in an easterly direction. The country may be divided into three classes, namely, that suitable for lucerne growing, without irrigation; that suited for cereals; and that which is not arable but provides really good natural pasture. This report deals with the results from the cereal crops in 1929-1930.

### THE SEASON.

Season 1929 must go down in our records as one of the most unfavorable experienced at Booborowie. The opening rains were light and distributed over a number of falls, with the result that the seed was sown in comparatively dry soil. However, a good germination resulted, and notwithstanding a winter rainfall below the average, crops made good headway until the end of September. From October 8th to November 17th only a few points were recorded, and crops were forced to maturity under most adverse conditions. Not only were the yields disappointing, but the quality of the grain also suffered.

In the following table the rainfall, month by month, comparatively with that for previous years and the average since 1900 is shown.

*Monthly Rainfall at Booborowie, 1900-29.*

| December ..  | 0.00         | 0.00         | 1.30         | 0.13         | 3.05         | 1.09                      |
| Totals..     | 16.36        | 17.79        | 13.17        | 16.91        | 13.44        | 17.48                     |

The total for the year is 13.44 inches, or 4.04 inches below the mean of 17.48 inches obtained for the period 1900-29.

September and December were the only months in which the fall exceeded the average, but that registered in the latter month was of no value to cereal crops. October and November were the critical months, the falls totalling 51 and 79 points respectively, whilst temperatures were high.

*Distribution of Useful Rainfall, 1900-1929.*

|---------------------------------|--------------|--------------|--------------|---------------|--------------|---------------------------|
| Seeding Rains (April-May) ..... | 2.82         | 5.41         | 1.47         | 2.69          | 1.39         | 2.80                      |
| Winter Rains (June-July) .....  | 3.61         | 2.58         | 4.54         | 5.59          | 3.07         | 4.56                      |
| Spring Rains (Aug.-Oct.) .....  | 5.30         | 8.47         | 3.64         | 4.48          | 4.36         | 6.05                      |
| Early Summer Rains (Nov.) ..... | 1.31         | 0.24         | 0.71         | 0.00          | 0.79         | 1.01                      |
| Totals .....                    | 13.04        | 16.70        | 10.36        | 12.76         | 9.61         | 14.42                     |

From the above table it will be noted that the "Useful Rainfall" amounted to 9.61 inches. On only one other occasion have crops had to develop under such low rainfall, namely, in 1914, when the total "Useful" was 7.79 inches.

Not only was the rainfall scanty, but during July and August frosts were frequent and severe, all tending to retard plant growth.

## HAY CROPS.

In all, 103 acres of cereal crops were cut for hay. This area was divided between nine fields, and made up of headlands and divisions cut between varieties.

The highest return was secured from Field No. 5, 1 ton 7cwt. 67lbs., and the general average amounted to 1 ton 1cwt. 17lbs.

The mean hay yield for the farm is 1 ton 19cwt. 55lbs. per acre.

## OAT CROPS.

The oat crops were sown on stubble land in the Rotation Plots. The season proved altogether unfavorable to oats, consequently crops developed poorly, and ultimately an average of 2bush. 16lbs. of grain was harvested. As a rule very good oat crops are secured in this district, and the farm average for the period 1915-1929 is 26bush. 34lbs.

## BARLEY CROPS.

Very poor growth characterised the barley crops, and from an area of 2.89 acres a return of 3bush. 33lbs. per acre was obtained. This is the lowest yield recorded in our averages, and is almost 21bush. below the mean return for the farm, namely, 25bush. 43lbs.

## WHEAT CROPS.

The wheat crops were seeded from the middle of May to the middle of June at the rate of 75lbs. of seed and 180lbs. 45 grade superphosphate per acre.

Notwithstanding the fact that the seeding period was unusually dry, a very satisfactory germination resulted. However, dry, hot, early summer weather settled all prospect of heavy yields, and not only were the returns low, but the quality of the grain was also poor.

A summary of the harvest is as follows:—

*Summary of Wheat Harvest.*

| Field.          | Variety.                      | Area.<br>Acres. | Total Yield<br>Bush. lbs. | Acre Yield<br>Bush. lbs. |

| "               | Federation (Rotational) ..... | 23.31           | 497 2                     | 21 19                    |
| "               | Federation (Manurial) .....   | 34.00           | 552 39                    | 16 15                    |
|                 |                               | 93.07           | 1,664 6                   | 17 53                    |
| Means .....     |                               | 169.89          | 2,898 12                  | 17 4                     |

The area harvested amounted to 169.89 acres, from which 2,898bush. 12lbs. of grain were secured, or an average of 17bush. 4lbs. per acre.

The best return was from Field No. 12. In this field only one variety was left for grain, the remainder being cut for hay. Bena was the variety, and gave 22bush. 18lbs. per acre. Considering the nature of the season this must be regarded as very satisfactory. Other good yields were Federation, 21bush. 19lbs., from the Rotation Plots; Sultan, 18bush. 39lbs.; and Dan, 17bush. 12lbs., from Field No. 13.

| 1924 .....  | 24.58                     | 19.37                      | 157.25          | 4,657 56                      | 29 37                        |
| 1925 .....  | 16.36                     | 13.04                      | 205.77          | 4,300 35                      | 20 54                        |
| 1926 .....  | 17.79                     | 16.70                      | 150.63          | 3,013 36                      | 20 0                         |
| 1927 .....  | 13.17                     | 10.36                      | 142.71          | 2,433 12                      | 17 3                         |
| 1928 .....  | 16.91                     | 12.76                      | 216.92          | 3,993 21                      | 18 25                        |
| 1929 .....  | 13.44                     | 9.61                       | 169.89          | 2,898 12                      | 17 4                         |
| Means ..... | 18.39                     | 15.09                      | 3,261.65        | 72,018 41                     | 22 5                         |

The return for this year, 17bush. 4lbs., is practically 5bush. below the average, but an examination of the rainfall figures will explain the cause of the low yield. The best average at Booborowie is 35bush. 24lbs., obtained in 1927, and the poorest, 2bush. 55lbs., secured in 1914, whilst the mean return for wheat is 22bush. 5lbs. per acre.

## WHEAT VARIETIES.

Each year a number of wheat varieties are submitted to test under identical conditions of soil and tillage in order that the yields secured may be compared one with the other.

This season the experiment was conducted in Fields 4, 5, 6, the plots each being at least two acres, and not more than five acres in area. All varieties were harvested after the rain which fell late in December.

The yields secured together with the mean figures for the 1924-29 period are submitted in the following table:—

*Wheat Varieties, Booborowie, 1924-29.*

| Variety.        | 1924. |    | 1925. |    | 1926. |    | 1927. |    | 1928. |    | 1929. |    | Mean<br>1924-29. |    |

| Defiance.....   | —     | —  | —     | —  | —     | —  | —     | —  | —     | —  | 11    | 25 | —                | —  |
| Ford .....      | —     | —  | 30    | 7  | 19    | 16 | 15    | 25 | 12    | 30 | 11    | 4  | —                | —  |

Federation heads the yields for this season, with a return of 23bush. 11lb. per acre. Next follows Major, 22bush. 7lbs., and Bena in third position with 21bush. 33lbs. Other varieties which exceed the 20bush. mark are Glode and Turvey with 20bush. 21lbs. and 20bush. 16lbs., respectively. These latter wheats are not as well known as those previously mentioned. Glode was bred at Roseworthy Agricultural College by crossing Gluyas with Federation, and therefore claims the same parents as Merredin. Turvey was a selection from Marshall's No. 3 made by Mr. Turvey, of Rochester, Victoria, and at one time was known by the name of Stump. The low yields from Nabawa, Ford, and Caliph were due to lodging, whilst Defiance shattered badly before harvesting. The average for the six-year period shows Merredin as the best yielder at Booborowie. This variety has a mean yield of 24bush. 17lbs. per acre.

Federation follows closely with 23bush. 59lbs., whilst Dan has the very creditable average of 23bush. 28lbs.

## EXPERIMENTAL PLOTS.

Permanent experiments have been conducted at Booborowie since 1916.

A full report of the Tillage and Manurial trials was published last year. This season we have no additional yields to record from these experiments, as owing to a reduction in the amount of money available for labor we were not able to afford the additional expense involved in reaping each plot separately, and in consequence the whole series were harvested in one block. However, the Rotational Experiments have received the usual attention, and the results secured over the 1917-29 period may now be reported upon.

## (C) ROTATIONAL EXPERIMENTS.

(Continued from Page 930.)

The systems of cropping included in these trials are as follows:—

|                    |                                                            |

| Five Course .....  | Bare fallow—Wheat, Lucerne, Lucerne, Lucerne               |

## MONETARY VALUES.

Any comparison of rotation experiments involves reducing the yields secured to a cash basis and deducting the expenses incurred. It is therefore necessary to arrive at a value for each crop, and also the cost of production. The Turretfield figures have been largely availed of, and the following are adopted in this report:—

|                                |                                                 |
|--------------------------------|-------------------------------------------------|
| Wheat .....                    | 4s. 6d. per bushel                              |
| Barley .....                   | 3s. 0d. per bushel                              |
| Oats .....                     | 2s. 6d. per bushel                              |
| Sheep grazing .....            | 11s. 7d. per head per annum (including rent)    |
| Cost of growing—               | £ s. d.                                         |
| Wheat on fallow .....          | 3 12 11 Exclusive of rent and manure            |
| Wheat on Sorghum Stubble ..... | 2 15 1 Exclusive of rent and manure             |
| Barley .....                   | 1 19 5 Exclusive of rent and manure             |
| Oats .....                     | 2 3 3 Exclusive of rent and manure              |
| Pease .....                    | 2 8 2 Exclusive of rent, manure, and harvesting |
| Rape .....                     | 1 18 0 Exclusive of rent and manure             |
| Sorghum .....                  | 3 0 0 Exclusive of rent                         |
| Rye Grass .....                | 0 5 0 Exclusive of rent                         |
| Lucerne .....                  | 0 16 6 Exclusive of rent                        |
| Rent .....                     | 0 12 6 per acre                                 |
| Superphosphate 36% .....       | 0 5 0 per cwt.                                  |

The values allotted call for some explanation:—

The value of 11s. 7d. for sheep grazing is the net revenue per head without any deduction being made for rent. This figure was obtained by deducting from the gross revenue for sheep at Turretfield, the cost of tending the flock, handfeeding, watering, marketing, incidentals, and inventory differences. The balance was divided by the average number of sheep carried, including lambs, hoggets, ewes, etc., and resulted in the amount adopted. No figures are available regarding the cost of growing wheat after a summer crop, and those relating to sowing after pease have been utilised. The cost of sowing rape has been considered equal to that of pease, except for the difference in the value of the seed.

The Rye Grass and Lucerne are each sown on the land prepared for the wheat crop, and the only charge made against these pastures is the cost of the seed plus 1s. 6d. per acre for broadcasting.

The summer crop receives a dressing of 10 tons of Farmyard Manure per acre, and an estimated cost of £3 per acre is probably on the conservative side.

Water is not laid on to each plot, and therefore it is difficult to graze the stubbles individually. Occasionally stubble grazing has been possible, and our records show a carrying capacity of approximately  $1\frac{1}{2}$  sheep per acre per annum. A flat rate of 15s. per acre has been adopted as the value of stubble grazing.

### SINGLE CROP.

In 1919 it was decided to set aside one plot for a permanent grazing test. This is natural pasture, and careful record has been kept regarding the stock it has carried.

A top-dressing of 1 cwt. 36 per cent. superphosphate was applied for the first time in 1924, and a similar quantity applied in each succeeding season. The results secured are shown below:—

Grazing returns from land not cropped, but left out as natural pasture:—

*Sheep Per Acre.*

|                           |         |         |                |

| Top-dressing              | .. .. . |         | 0 4 4          |
| Rent                      | .. .. . |         | 0 12 6         |
|                           |         |         | 0 16 6         |
| Total expenditure         | .. .. . |         |                |
| Profit per acre per annum | .. .. . |         | 0 9 11         |

Over the 11-year period the natural pasture has carried 2.28 sheep per acre per annum, which at 11s. 7d. per head equal an annual return of £1 6s. 5d.

The top-dressing costs 8s. per acre (5s. for manure, 3s. for drilling), but as this has only been applied since 1924, an average cost of 4s. 4d. per acre must be deducted for this item.

When rent is also taken into consideration, the profit per acre from permanent grazing amounts to 9s. 11d. per acre.

### TWO COURSE ROTATIONS.

Two forms of Two Course Rotations are undergoing test, and the results from the Bare-Fallow-Wheat system, which may be regarded as the standard for comparison of rotations, are submitted in the following table:—

*Returns from Wheat grown continuously after Bare Fallow, with 2cwt. Superphosphate per acre.*

| Year.                | Grain per Acre |           |

## **TOP BRAND FERTILIZER APPEAL.**

I came from the depths of the earth, from the waters of the sea, from the atmosphere we breathe. My sources are worldwide.

I offer myself as a servant of the Primary Producer, and, in the end, I am free—I pay for myself several times over.

I feed the plants, increase the yield, lower cost of production, make labour more profitable, and release land needed for other purposes.

I make two blades to grow where one grew before, providing feed and food where hunger would prevail. I make possible profit where otherwise loss would accrue. And, while I serve, I leave with the soil a portion of myself which forms a residual asset for years to come.

Plants, like all other forms of life, must feed. It is my function to furnish food for plant life.

I am a service. All I need is an opportunity to show what I can do. Experiment stations throughout the land have given me this opportunity—have tried me out and found my ability not wanting. Farmers everywhere testify to my power.

I am the farmer's friend and mankind's benefactor.

I am "TOP BRAND SUPER."

**TOP SPECIAL SUPER (45% W.S.P.)**

**NOTED FOR ITS DRILLABILITY.**

**THE ADELAIDE CHEMICAL & FERTILIZER CO. LTD.**

| Profit per acre per annum . . . . .         |  | <b>0</b>  | <b>14</b> | <b>1</b>  |

From the above table it will be seen that the average yield from land regularly cropped every other year and fallowed in the alternate years is 26bush. 53lbs.

With wheat at 4s. 6d. per bushel this equals £6 1s. per acre. The stubbles at Booborowie are thick and flaggy, and the grazing value amounts to 15s. per acre. In addition, there would be a certain amount of early winter, and at times fallow grazing, but as we have no means of measuring these items, the total receipts consist of those from the crop and stubble grazing, amounting in all to £6 16s.

The expenditure comprises the cost of growing the wheat crop and rent for two years. This leaves a credit balance of £1 8s. 1d. for the rotation, or 14s. 1d. per acre per annum.

*Returns from Wheat after Summer Crop, comparatively with Wheat after Bare Fallow,*  
1917-1929.

| Profit per acre per annum .....   | 0 13 5                      |    | loss 0 3 4                  |    |                                            |      |

In the above two-course rotation the wheat crop is preceded by a summer crop instead of Bare Fallow. The summer crop, formerly sorghum, but of recent years Sudan grass, is sown in rows and kept well cultivated. It is regularly dressed with 10 tons of

farmyard manure per acre, and the wheat crop receives a dressing of 2cwt. 36 per cent. superphosphate. The development of the summer crop has not been particularly successful. In the years 1920 and 1921 good growth resulted, the grazing amounting to 3.49 and 4.53 sheep per acre respectively. However, in both 1917 and 1927 the summer crop was a complete failure, whilst practically no feed was obtained in 1928.

Everything depends on the summer rainfall, which at Booborowie is very irregular.

The average carrying capacity of the summer crop in this rotation is 1.60 sheep per acre, which at 11s. 7d. per head amounts to 18s. 6d. as the value for the crop. The cost of sowing when dressed with 10 tons of farmyard manure has been estimated at £3 per acre, and notwithstanding the fact that the soil preparation reduces the subsequent cost for the wheat crop, it is evident that Sudan grass has proved a very expensive crop in this district. Comparing the wheat yields obtained after bare fallow, and after a summer crop, it will be observed that the former amounts to 26bush. 36lbs. per acre, and the latter 24bush. 24lbs. The summer crop has therefore had the effect of depressing the yield by 2bush. 12lbs.

When all receipts and expenditure have been taken into consideration, the profit per acre from the bare fallow—wheat rotation is 13s. 5d. per acre, and the loss on the summer crop—wheat rotation 3s. 4d., making a difference of 16s. 9d. in favor of the former. The application of 10 tons of farmyard manure is very costly, and if this is ignored the debit balance against the summer crop rotation is practically wiped out. Moreover the Sudan grass provides grazing at a time of the year when green fodder is most valuable.

#### THREE-COURSE ROTATIONS.

In addition to a number of three-course rotations in which the land is sown with a secondary crop in the third year, we have another series—bare fallow, wheat, pasture—the latter comprising the natural grazing which springs up spontaneously after the wheat crop.

With this system of cropping, opportunity was taken of testing the influence of various dressings of superphosphate on the wheat yield, and subsequent residual effect on the pasture which follows in the grazing year. The results obtained are set out in the following table:—

*Returns from Bare Fallow, Wheat, Pasture Rotation in which the Wheat Crop is regularly dressed with varying quantities of Superphosphate, 1917-1929.*

Dealing with the wheat yields received from the varying applications of superphosphate. From the above figures, it will be seen that the 1cwt. dressing has given the best return with an average of 30bush. 7lbs. This exceeds the 2cwts. dressing by 46lbs., but there is not much variation between the yields from any of the remaining plots receiving manure, the ½cwt. dressing giving 29bush. 5lbs.; the 2cwts., 29bush. 21lbs.; and 3cwts., 28bush. 42lbs.

However, there is a marked increase with even small dressings of superphosphate, the No Manure plot only averaging 17bush. 7lbs. per acre. After deducting the cost of the manure (5s. per cwt.), when the crop alone is taken into consideration, the most profitable application is 1cwt. of superphosphate. The pasture in the grazing year receives no additional manure, and we now have to examine the residual effect of the superphosphate applied with the wheat crop on the grazing which follows. The figures show that the greatest number of sheep have been carried on the pasture preceded by a wheat crop receiving 3cwts. superphosphate. Except that the sheep-carrying capacity following the ½cwt. and 1cwt. applications is practically equal, there has been a gradual increase in grazing with the quantity of manure utilised. Thus contrary to the grain yields, the maximum pasture has followed the heaviest dressing of superphosphate. The fact that the number of sheep carried average 2½ head per acre per annum illustrates the grazing quality of Booborowie land. When both the value of the crop and grazing yields are taken into consideration, the total monetary return shows that the greatest cash revenue is secured from the series in which the wheat crop receives a dressing of 2cwts. of superphosphate. However, when the expense of cropping and the rental of the land is deducted, the most profitable rotation is that in which the wheat secures 1cwt. of manure. On a per acre basis the No Manure has returned a profit of 3s. 5d.; ½cwt. superphosphate, £1 2s. 3d.; 1cwt., £1 2s. 8d.; 2cwts. £1 1s. 2d.; and 3cwts., 18s. 7d.

| Profit per Acre per Annum .....   | 0           | 15 | 4       |    | 1           | 5  | 0     |    | 0           | 2  | 10       |             | 0       | 4        |

In these rotations the wheat crops receive a dressing of 2cwt. 36 per cent. superphosphate, and the barley, oats, pease, or rape a lewt. application.

The highest wheat yield has been obtained from the Bare Fallow, Wheat, Oats rotation, namely, 30bush. per acre, and the lowest yield 27bush. 8lbs. from the system of cropping including barley. It is difficult to account for the variations in wheat yield from the four rotations under review, as if the secondary crop had influence it would be reasonable to anticipate that the highest return would be secured from the rotation including a leguminous crop such as pease.

The barley crops have not been satisfactory, averaging only 16bush. 13lbs. per acre.

Oaten crops have yielded consistently better, and show a mean return of 27bush. 18lbs.

The grazing from the pea and rape crops has fluctuated considerably according to the character of the season, being particularly good in 1921. The mean returns are 2.32 and 1.76 sheep per acre respectively.

It will be noted that on the line dealing with stubble grazing, the value of two stubbles has been credited to those rotations including two cereal crops. The carrying capacity of both oaten and barley stubble has been considered equal to that of wheaten stubble.

The cost of producing the various crops and the rental value of the land occupied has been calculated, and after deduction from the total receipts a net profit per acre of £1 5s. for Bare Fallow, Wheat, Oats rotation; 15s. 4d. for Bare Fallow, Wheat, Barley; 2s. 10d. for Bare Fallow, Wheat, Pease; and 4s. 2d. for Bare Fallow, Wheat, Rape is shown. These figures are comparative with £1 2s. 8d. secured from the Bare Fallow, Wheat, Pasture rotation as given in the previous table. The small net profit from the rotations in which special preparation of the land is necessary for the sowing of the grazing crop illustrates the necessity of high grazing returns if this practice is to prove profitable.

For example, the pea crop cost £2 13s. 2d. to seed. With sheep grazing valued at 11s. 7d. per head, this means that almost five sheep per acre must be pastured in order to cover expenses.

#### FOUR-COURSE ROTATIONS.

The are three four-course rotations undergoing test. The wheat crop is preceded by a year of bare fallow, and in two series is followed by a second cereal crop, barley and oats, then left out as pasture for one year before being fallowed again. In the third series the wheat crop is followed by pasture for two years. The grazing in this case consisting of Italian Rye Grass sown at the rate of 9½lbs. per acre in the stubble of the wheat crop. The cereals, wheat, barley, and oats each receive a dressing of 2cwt. 36 per cent. superphosphate per acre, but the pasture is not manured.

*Returns from Four-Course Rotations—Bare Fallow, Wheat, Barley, Pasture; Bare Fallow, Wheat, Oats, Pasture; and Bare Fallow, Wheat, Rye Grass, Rye Grass (1917-29).*

As in the case of the three-course rotation, the highest wheat yield has been secured from the rotation where oats is the secondary crop. Here the return is 29bush. 55lbs. per acre, as compared with 27bush. 23lbs. and 26bush. 36lbs., from the rotations including Barley and Rye grass respectively.

The barley yield is fairly satisfactory, being almost 19bush., and the average for oats is 25bush. 29lbs. The Italian Rye Grass has yielded very good grazing, the average carrying capacity being 2.20 sheep per acre in the first year and 2.82 in the second, making a mean annual return of 2.51 sheep.

The poorest grazing years were 1927 and 1929, when the return from the rye grass was only 0.64 sheep per acre per annum. On the other hand, 1920 and 1921 were good pasture seasons, and the rye grass grazing amounted to almost five sheep per acre. The mean figures for the natural grazing in the pasture year in the other systems are 1.65 and 1.81 sheep per acre.

## Metropolitan Abattoirs, Adelaide.

MANUFACTURERS OF

### Meat Meal for Pigs.

Read Report of trials made by PROF. PERKINS, *Journal of Agriculture*,  
January and July, 1921.

### Meat Meal for Poultry.

The money value of all produce has been calculated, and after allowance is made for the various items of expenditure, the Bare Fallow, Wheat, Oats, Pasture rotation shows a net profit of 15s. 11d. per acre, the Bare Fallow, Wheat, Rye Grass, Rye Grass 13s. 9d., and Bare Fallow, Wheat, Barley, Pasture 11s. 9d.

#### FIVE-COURSE ROTATION.

Only one five-course rotation is included in the plan of experiment. It consists of a single wheat crop, preceded by bare fallow, and followed by three years of lucerne pasturage. The lucerne seed is broadcasted at the rate of 6lbs. per acre in the wheat stubble, and lightly covered. The wheat crop is manured at the rate of 2cwts. superphosphate per acre, but the lucerne receives no additional fertiliser.

*Returns from Five-Course Rotation—Bare Fallow, Wheat, Lucerne, Lucerne, Lucerne, (1917-29).*

| Profit per acre per annum .....         |        |    | 0                  | 14                  | 2                  |

The average wheat yield from this rotation is within a pound of 29bush.

The lucerne has provided first-class grazing, and in 1920 the third-year crop carried almost six sheep per acre. In this year the summer rainfall was fairly high, and even first-year lucerne yielded grazing for three sheep per acre per annum.

The quantity of fodder increases with the age of the crop, averaging 1.67 sheep per acre in its first year, 2.32 in the second, and 2.69 in the third. The annual grazing is therefore 2.23 sheep per acre.

The total receipts amount to £11 2s. 10d., and expenses, including rent, £7 11s. 11d.

The balance in favor of this rotation thus becomes £3 10s. 11d., or a profit per acre of 14s. 2d.

## SUMMARY OF ROTATIONS.

In order that the comparative values of the different rotations may be conveniently studied, the mean annual profits from each form of rotation have been summarised below:—

*Summary of Mean Annual Profits from Rotations Tested at Booborowie, 1917-29.*

| Rotation.                                                       | Annual Profit<br>per Acre. |

| " " . Bare Fallow, Wheat, Oats .....                            | 1 5 0                      |
| " " . Bare Fallow, Wheat, Pease .....                           | 0 2 10                     |
| " " . Bare Fallow, Wheat, Rape .....                            | 0 4 2                      |
| Four Course . Bare Fallow, Wheat, Barley, Pasture .....         | 0 11 6                     |
| " " . Bare Fallow, Wheat, Oats, Pasture .....                   | 0 15 11                    |
| " " . Bare Fallow, Wheat, Rye Grass, Rye Grass ..               | 0 13 9                     |
| Five Course.. Bare Fallow, Wheat, Lucerne, Lucerne, Lucerne     | 0 14 2                     |

The three-course rotation Bare Fallow, Wheat, Oats has given the largest annual profit, namely, £1 5s. per acre. This is a form of cropping commonly availed of in the Booborowie district, and from the figures quoted appears to be a practice which is well justified.

Another three-course rotation—Bare Fallow, Wheat, Pasture—has shown the very satisfactory profit of £1 2s. 8d. per acre.

In addition, the rotations Bare Fallow, Wheat, Oats, Pasture; Bare Fallow, Wheat, Barley; and Bare Fallow, Wheat, Lucerne, Lucerne, Lucerne, have each given a greater mean profit than Bare Fallow, Wheat, which is accepted as the basis for comparison of rotational experiments.

Where expense is incurred in sowing a grazing crop such as Sudan grass, Pease, or Rape the profits have been materially reduced.

## CLEARING THAT SCRUB.

CAMPBELL'S

**PATENT SCRUB RAKE**  
WILL DO THE WORK OF 15 MEN, AND  
DO IT BETTER.

Scrub Rollers, Fire Rakes (all sizes), Tubular Sack Trucks and Bag Elevators, Wheelbarrows, Earth Scoops, Etc.

## SPRAYING EXPERIMENTS FOR THE CONTROL OF GREEN PEACH APHIS (*Myzus persicae*) CARRIED OUT AT THE BLACKWOOD EXPERIMENTAL ORCHARD, 1929.

[By R. FOWLER, Manager, Adelaide and Coromandel Valley Experimental Orchards.]

This aphid first made its appearance in large numbers in the Experimental Orchard in 1924, and that year did a very considerable amount of damage in practically all the peach orchards in this and other States. In 1925, a number of winter spraying tests were made, but as, in the following Spring, the infestation was a very light one, no very pronounced results were obtained, and in the Winter, owing to pressure of other work, and a false sense of security from attack, the winter sprays were not continued. This was rather unfortunate, as it happened, because in 1929 another epidemic occurred, which almost threatened to wipe out the peach trees themselves, and caused untold loss to peach growers in South Australia, Victoria, and New South Wales. In the winter of 1929 spraying tests were again taken up, and new preparations tried.

Before dealing with the results, a few words about the life history of the insect will perhaps help us to understand more fully why a spray applied in the Winter has some chance of success.

Considerable interest attaches to the green aphid species, as it furnishes a striking example of the summer migration of aphids to different food plants. This species, during the Summer, feeds upon various vegetables and plants. We are told by Entomologists, who have studied its life history, that the Winter is usually passed in the egg stage on the peach, though the wingless females may sometimes persist on the summer food plants, if weather conditions are not too severe. The eggs hatch very early in the Spring, so that the young stem mothers from them are often almost fully grown before the earliest peach blossom appears. About the time the buds begin to open the stem mothers begin to give birth to living young. Very few of this brood attain wings, but the third generation mostly become winged and begin to leave the peach trees on which they were born, about November, and by early December have almost completely left the peaches and gone to their Summer food plants.

- According to observations made by E. P. Taylor, in America the Spring generations of the peach become fully grown in about two weeks, and an individual aphid lives about a month. The winged females were observed to return to the peaches at Blackwood in the very late autumn, when most of the leaves were falling.

Numerous specimens were under observation, both last Autumn and this, and each was noticed to have a small colony of young, from eight to 10, which grew in size very rapidly. These developed into wingless females. The true males to fertilise these females are winged and migrate from the Summer plants, we are told. It is from these females that we get the Winter eggs which, as before stated, give rise to the stem mothers which start the Spring generation.

With this definite information regarding the life history of green aphid, we know that the eggs are on the trees during the Winter, and probably can be reached with a Winter spray to destroy them, and that before the buds actually burst, and when strong sprays may still be used. The wingless female that gives rise to all the subsequent broods is also exposed to attack, and, therefore, when applying sprays at this time, we are attacking the insects with the most chance of effectively checking them. We all know the difficulty of doing this once the colonies are established in the newly-formed leaves.

The tests at Blackwood were designed with the idea of proving if a Winter spray would materially assist in peach aphid control, and which of a number of suggested

washes would give the best results. The tests were nine in number. Each test consisted of two rows of peaches, each containing 20 trees of various varieties, 28 of which were sprayed, and 12 were left as check trees.

The sprays used were (1) Volek Oil, 2 per cent. Solution; (2) Kleenup, 4 per cent. Solution (this is a winter spray oil prepared by Volek); (3) Gargoyle Special Spraying Oil, 1 in 25; (4) Gargoyle Red Spraying Oil, 1 in 25; (5) French's Formula (1gall. oil, 1 pint Black Leaf 40, 1lb. soft soap to 100galls. of water); (6) 1 pint Black Leaf 40, 4lbs. soft soap to 100galls. of water; (7) Lime Sulphur, 1 in 12; (8) Rustica Salis (an Italian preparation); (9) Atomol Tobacco Dust, 3 per cent.

The sprays were all applied on August 6th, 1929, when most of the flower buds were just commencing to swell. Two or three of the early flowering varieties were out in full bloom, and suffered rather severely from the oil sprays. The dusting was done on September 11th when the buds were more fully expanded.

As the experiments were carried out in part of the variety collection, it was obviously impossible to get any definite crop record, but notes were made from observations from time to time. Green aphid appeared in the Spring in fair numbers, but nothing like the infestation of the previous year.

In Tests 1, 2, 3, and 4 where oil sprays were used, the results were very satisfactory, very little green aphid being noticeable, while some of the unsprayed check trees were rather badly infested. There was also an appreciable difference in the appearance of the foliage on the oil-sprayed trees, the leaves being larger, healthier, and of a darker green color than on the check trees. French's Formula in Test 5 displayed good control of the aphid, but did not affect the appearance of the trees as in Tests 1-4. In Test 6 Black Leaf 40 and soap, the sprayed trees showed few aphids, although some of the check trees were infested. The foliage did not appear to be affected. Considerable trouble was experienced with this mixture in the spray pump. The valves stuck continually, with resultant loss of pressure. Lime Sulphur 1 in 12 in Test 7, apparently was not as effective as the oils or the Black Leaf 40, and there was no noticeable difference in the appearance of the trees.

Rustica Salis in Test 8 gave no outstanding results. Atomol Dust in Test 9 gave rather poor results from Winter use only, more green aphid being noticeable in the rows treated than in any other of the Tests, with little apparent difference between the treated and the check trees. We know from previous trials that better results are obtained with this Dust later, when the insects are more numerous on the trees.

During the coming season two new winter washes imported from England are to be tried, No. 1 being Wm. Cooper & Nephews Limited Tar Distilled Wash, and No. 2 a similar preparation called "Mortegg," put up by Murphy & Son. These washes are reported to have given good results in England, New South Wales, and New Zealand against various pests.

## PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1930.

### Eggs for Hatching and Day-old Chickens.

WHITE LEGHORNS ONLY. DELIVERY—JULY, AUGUST, and SEPTEMBER.

#### PRICES—

EGGS—10s. per Setting of 15 Eggs; Incubator Lots, £2 10s. per 100.

DAY-OLD CHICKENS—17s. 6d. per dozen, £6 per 100. Free on rail, Salisbury.

## EGG-LAYING COMPETITION CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

### WINTER TEST.

The Winter Test of the Egg Laying Competition conducted at Parafield Poultry Station, concluded on July 31st, a period of 122 days.

### EGG WEIGHING.

In order to qualify for continuance in the competition the regulations stated:—"That every egg laid by each bird from July 1st, to July 31st, 1929, will be weighed the day after it is laid. Qualifications for the purpose of this test shall be that 60 per cent. of the eggs laid during July, 1929, must be 2ozs. in weight or over." Therefore, the scores of all birds failing in the weight of eggs have been dropped. The number of birds disqualified for under-weight eggs is as follows:—

Section 1—White Leghorns and any other light breed, 32 from 207 birds competing.

Section 3—Black Orpingtons, 19 from 30 birds competing.

Section 4—Any other heavy breed, no rejections.

The average production per bird in each section is as follows:—

Section 1—White Leghorns, 56 eggs per bird, which is equivalent to 45 per cent.

Section 1—Any other light breed, 44 eggs per bird, which is equivalent to 36 per cent. production.

Section 3—Black Orpingtons, 58 eggs per bird, which is equivalent to 47.5 per cent.

Section 4—Any other heavy breed, 38 eggs per bird, which is equivalent to 31 per cent.

The average production for all birds under test was 56 eggs.

The following are the leading scores in each section from April 1st to July 31st:—

### RED COMB EGG ASSOCIATION, INCORPORATED.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

### CONFERENCE OF UPPER NORTH BRANCHES.

Branches of the Agricultural Bureau in the Upper North Districts of the State met in Conference at Tarcowie on Thursday, July 17th. Messrs. F. Coleman (Chairman Advisory Board of Agriculture), Professor Perkins (Director of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), A. H. Robin (Government Veterinary Officer), E. L. Orchard (Agricultural Instructor), J. O. Hatter (Dairy Instructor), H. C. Pritchard (General Secretary Agricultural Bureau), and F. C. Richards (Assistant Secretary) represented the Department of Agriculture. There was a large attendance of delegates from the following Branches:—Caltowie, Laura, Tarcowie, Wirrabara, Appila-Yarrowie, Booleroo Centre, Wepowie, Gladstone, Morehard, Willowie, Ororoo, Eurelia, Murraytown, Black Rock, Eurelia Women's, Jamestown, and Yandiah. Mr. H. F. Ninnies, of the Tarcowie Branch, presided, and extended a cordial welcome to officers of the Department and delegates from neighboring Branches. Mr. F. Coleman (Chairman of the Advisory Board of Agriculture) delivered the opening address.

The following papers were read and discussed:—"Power Farming," Mr. W. Ninnies (Tarcowie); "The Other Side of the Tractor Question," Mr. P. Curnow (Wirrabara); "Mechanical Work as a Necessary Part of Farm Knowledge," Mr. C. Stott (Eurelia); "Buy Australian Goods," Mr. E. Rooke (Wepowie); "Animals on the Farm," Mr. C. Schultz (Morehard); and "The Registration of Bulls," Mr. C. Knauerhase (Wepowie).

It was decided to hold the 1931 Conference at Willowie. On the motion of Mr. S. McCallum (Willowie), seconded by Mr. A. McCallum (Willowie), it was decided—"That this Branch ask Conference to request the Waterworks Department to deliver or post the readings of meters to all who rent meters, instead of attaching readings to meters." Mr. Crocker (Wepowie) moved and Mr. Orrock (Wepowie) seconded—"That the attention of the Government be drawn to the unnecessary delay in dealing with applications for assistance under the Drought Relief Act and paying for seed wheat supplies."

Mr. F. Coleman (Chairman of the Advisory Board of Agriculture) presented to Messrs. C. Knauerhase and T. Orrock (Wepowie) and B. S. McCallum and H. Kupke (Morehard) certificates conferring on them the honor of life membership of the Agricultural Bureau of South Australia. Mr. Coleman also presented the following trophies won in the 1929-30 Upper North Crop Competition:—First prize, case of stainless cutlery, Mr. M. E. Meaney, 87 points, and E.P. cake dish, presented by the Cresco Fertiliser Coy.; second prize, Mr. L. Noonan, 86.5 points, E.P. fruit dish and a silver cup, presented by the Superphosphate Association of South Australia.

The evening session was occupied by addresses delivered by Messrs. W. J. Spafford (Deputy Director of Agriculture) and A. H. Robin (Government Veterinary Officer). The Conference concluded with a supper and dance.

### CONFERENCE AT CEDUNA.

The Annual Conference of Branches of the Agricultural Bureau situated in the western portion of Eyre Peninsula was held at Ceduna on Wednesday, July 2nd. The Department of Agriculture was represented by Messrs. A. M. Dawkins and S. Shepherd (Members of the Advisory Board of Agriculture), Professor A. J. Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. T. McKenna, B.V.Sc. (Government Veterinary Officer), W. H. Brownrigg (District Agricultural Instructor), and H. C. Pritchard (General Secretary). There was a large and representative gathering from the following Branches:—Laura Bay, Mudamukla, Petina, Maltee, Koonibba, Goode, Nunjikompita, Charra, and Smoky Bay.

Mr. E. D. Barnett (Chairman of the Laura Bay Branch) presided, and the opening address was delivered by Mr. A. M. Dawkins (Member of the Advisory Board). During the course of the Conference the following papers were read and discussed:—"Care of Farm Horses," Mr. H. Jones (Goode); "Improving the Fertility of the Soil," Mr. J. Spry (Laura Bay); "Young People on the Farm," Mr. W. Edson (Laura Bay).

A large number of questions were answered by departmental officers, and the following resolutions were carried:—1. "That this Branch is in favor of the Instructor of Agriculture being stationed in a more central position." 2. "That the next Conference be held at Coduna, and that the Goode Branch be responsible for the arrangements."

During the evening session, at the request of the Branches constituting the Conference district, Professor A. J. Perkins (Director of Agriculture) delivered an address, "The Objects of the Compulsory Wheat Pool."

## VEGETABLES

*good health demands them!*

Only by eating vegetables frequently can we maintain our blood in good condition, and therefore, our health. This fact is not sufficiently realised.

Made in handy tablet form, Swallow & Ariell's Compressed Vegetables are equal in every way to fresh, as only water is removed, and their true flavour is retained. Easily prepared and economical—one pound of the compressed article goes as far as ten of the fresh—they take up so little space that they're easily stored.

With this product of Swallow & Ariell at hand you need never be short of health-giving vegetables. Buy a few packets now!

**SWALLOW & ARIELL'S  
COMPRESSED  
VEGETABLES**

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, July 30th, there being present Messrs. F. Coleman (Chairman), H. N. Wicks (Vice-Chairman), H. S. Taylor, P. H. Jones, A. J. Cooke, G. Jeffrey, R. H. Martin, J. W. Sandford, A. L. McEwin, Dr. A. E. V. Richardson (Director Waite Research Institute), and H. C. Pritchard (Secretary). Apologies were received from Mr. A. M. Dawkins, Professor A. J. Perkins, and Mr. W. R. Birks.

*Election of Officers.*—Mr. F. Coleman was re-elected Chairman and Mr. H. N. Wicks Vice-Chairman.

*Re-appointment of Members.*—The Secretary reported that Messrs. F. Coleman, H. N. Wicks, A. J. Cooke, A. M. Dawkins, P. H. Jones, and H. S. Taylor, who retired by the effluxion of time on June 30th, had been re-appointed for a further period of two years by the Hon. Minister of Agriculture.

*Experimental Work at Berri Orchard.*—Mr. Geo. Quinn (Chief Horticultural Instructor), in reporting on a resolution requesting that experiments might be conducted at the Berri Orchard on crops other than fruit trees and vines, which was carried at the River Murray Conference, said the matter of trying out economic crops had not escaped consideration.

A few years ago cotton was tried, the growth recorded, and a careful account kept of the costs of production and revenue received from a plot, which was fully reported upon at the time. Sugar beet was also tested, and the resulting growth of the plants noted. The possibilities of growing rice, peanuts, haricot beans, &c., was also gone into, but their cultivation not undertaken. Besides the heavy general costs of production, the great barrier to the general adoption of such crops was the outstanding fact that the contours of the land, and means of watering these irrigation areas in South Australia, had been designed wholly for deep rooting, perennial plants, such as trees and vines, which had been proved to be capable of standing for comparatively long periods between waterings. In California and other American States, as well as in the Murrumbidgee irrigation areas of New South Wales, where some of these crops succeed, water was available practically whenever it was desirable to apply it to the plants. Most of these annual or shallow-rooted heat-loving plants could be brought to a successful degree of production only where water could be given them at least once each week. To make trials with them or any similar crop possible at the Experimental Orchard, would involve expenditure on an efficient pumping plant costing probably several hundreds of pounds.

*Standardisation of Sultana Drying Methods.*—In accordance with a resolution carried at the Berri Conference, a copy of Mr. Arndt's paper on the above subject was forwarded to the Australian Dried Fruits Board, from whom the following reply was received:—"Referring to your letter on the subject of standardisation of sultana drying methods, I have to advise that this matter was very fully considered by the Australian Dried Fruits Board at a meeting held in Melbourne, and it has been decided to arrange a meeting of packers from the various States, to be held at Mildura during the second week in September, with a view to arriving at definite recommendations for the 1931 season."

*Stimulating Rainfall.*—Following the inquiry of the Board into the possibilities of research work being undertaken to determine the feasibility of stimulating rainfall, the Commonwealth Meteorologist furnished the reply set out hereunder:—"My opinion on the question is that Nature's allied forces operating in times of stress on Australia are far too vast and powerful to warrant any hope of their being overcome to such an extent as to be of material economic value. Consequently no experiments (other than laboratory) have been carried out by this Bureau. A number of proposals for producing or stimulating rain have been submitted to the Bureau, but as yet none has been considered to be of any practical value. On several occasions in past years experimentalists, not connected with this Bureau, have endeavored to produce rain over various parts of Australia, but without success. In this connection Mr. Balsillie's

experiments are mentioned:—“During 1916 and 1917 the late Mr. J. Graeme Balsillie, A.M.I.E.E. (with the assistance of a Government subsidy) carried out “Rain Making by Electricity” experiments at a few stations situated in the dry areas of Australia. A Rain Precipitation Investigation Committee was appointed by the New South Wales Government to report upon Mr. Balsillie’s experiments; the members of the Committee being:—Professor T. W. E. David (Chairman); Professor Charles E. Fawsitt; Mr. O. W. Brain, Chief Electrical Engineer for New South Wales Railways; Professor Oscar U. Vonwiller; Professor W. E. Cooke, Government Astronomer; Mr. Wm. Corin, Chief Electrical Engineer for Public Works, New South Wales; and Professor J. P. V. Madsen. The final report of the Committee presented to the Premier of New South Wales read as follows:—Resolution—That in view of the difficulty at present of our continuing the investigation with any advantage it should be closed. The Committee also desires to inform the Premier that inquiries made from the Commonwealth Meteorologist, Mr. H. A. Hunt, have resulted in information being obtained to the effect that meteorological observations taken over a period of Mr. Balsillie’s experiments absolutely fail to support in the slightest degree his claims that rainfall had been stimulated by the means which he had adopted.” The following entry was made in the minute book:—In closing the investigation the Committee places on record the fact that no information whatever has been submitted for the consideration of members which justifies the claim that any advance has been made in Australia in the direction of causing or increasing rainfall.”

*Conference Resolutions, Ceduna.*—“That this Branch (Goode) is in favor of the Instructor in Agriculture being stationed in a more central position.” It was decided to submit the resolution to the Director of Agriculture for a report.

*Conference Resolutions, Tarowrie.*—(a) “That conference requests the Waterworks Department to deliver or post the readings of meters to all who rent meters instead of attaching readings to meters.” The Secretary was instructed to ascertain from the Waterworks Department if there was any reason why the proposal should not be adopted. (b) “That the attention of the Government be drawn to the unnecessary delay in dealing with applications for assistance under the Drought Relief Act and paying for seed wheat supplies.” It was decided to submit the resolution, together with a statement from a delegate at the Conference, to the State Bank.

*Observance of Fruit Pests Act.*—At the 1930 River Murray Conference a resolution was carried asking that steps be taken by the Department to enforce the Fruit Pests Act, especially in regard to codlin moth. Mr. Geo. Quinn (Chief Horticultural Instructor), to whom the resolution was forwarded, outlined the action he proposed to adopt in connection with the resolution.

*Instructors Judging at Country Shows.*—A resolution was received from the Blyth Branch asking the Department to reconsider its decision in not permitting District Instructors to judge at country shows. It was decided to refer the resolution to the Director for a report.

*Press Statements Concerning Agricultural Expenditure.*—Mr. H. N. Wicks drew attention to a statement that had appeared in the press referring to the amount expended by the State at the Experimental Farms and Orchards. Members present referred to the excellent research work that was being done at the institutions conducted under the administration of the Department of Agriculture, and it was decided, on the motion of Mr. Taylor, to forward the following resolution to the Hon. Minister of Agriculture:—“That in view of recent public statements respecting State establishments for agricultural education and research, this Board desires to record its conviction of the paramount necessity in a rural community such as South Australia of stimulating scientific research and education in agriculture.”

*Pruning Competitions.*—The Secretary was instructed to forward a letter to the Royal Agricultural and Horticultural Society, the Superphosphate Association of South Australia, Messrs. Gibbs, Bright Pty Co., Ltd., Nitrogen Fertilizers Pty. Co., Ltd., and W. Langdon Parsons, Esq., expressing the thanks and appreciation of the Advisory

Board for trophies donated to the championships of the River Murray and Lower North Pruning Competitions.

*Crop Competitions.*—In reply to a question asked by Mr. P. H. Jones, the Secretary intimated that although the subsidy for Wheat Crop Competitions had been withdrawn, the Department of Agriculture would co-operate, as far as possible, with District Committees in the continuing of the Competitions.

*Life Member.*—The name of Mr. J. S. Hammatt, of the Lyndoch Branch, was added to the roll of life members of the Agricultural Bureau.

*New Branches.*—Approval was given for the formation of Branches at Parilla (Women's), Upper Wakefield (Halbury), and Kyancutta, with the following as foundation members:—Parilla—Messdames C. Phillis, H. Johnston, C. R., and F. Kerley, S. Leane, C. Neindorf, C. Dabinett, A. Thompson, E. Howie, J. McCabe, G. Plew, R. Daniel, E. Pillifeant, R. Dawneey, J. Eckert, C. Hancock, J. Barry, F. Johnson, F. Smith, J. Seidel, A. Welden, Misses R. Phillis, M. Plew, E. Colwill, T. Seidel, H. and E. Johnson; Upper Wakefield (Halbury)—Messrs. W. Sanders, J. L., J., and B. Cleary, E. and C. Roberts, H. Simon, F. Neumann (2), M. Kiley, E. Martin, P. Higgs, M. Lally, J. Hartnett; Kyancutta—Messrs. C. Kammermann, H. Walters, R. Bedford, W. Mitchell, T. Holman, E. Kelly, H. McKenna, G. Dolan, R. Alsop, J. and E. Dyke, H. Longmire, J. and T. O'Loughlin, L. and F. Daniels, C. and A. Laube, R. Sampson, R. Miller, A. Cook, D. Fitzgerald, H. Little, B. Peters.

*New Members.*—The following names were added to the rolls of existing Branches:—Blackheath—A. McLellan; Morchard—H. R. Lillecrapp, A. C. Smith, P. Rhyne; Kulyan—Mr. Ritchie; Yeelanna—H. Owen, A. L. Carslake, G. Boumont, E. Manual; Yadanarie—L. S. Tyler; Poochera—F. R. Joy; Monarto South—J. L. Lofthouse, E. O. Gogel; Koppio—O. Tozer, S. Cooper, Hy. Tucknott, John Tucknott, W. C. Fogden, John Fogden, Frank Barraud; Wudinna—J. Bailey, L. Rowley; Murray Bridge—E. Butler; Wirrilla Women's—Mrs. S. Garrard; Nantawarra—K. W. Young; Bundaleer Springs—F. Officer, D. Mahoney; Clare—L. W. Butler, M. McEvoy, J. Lloyd, H. W. Lawrence, F. M. Ashby, R. McFeat, A. Phoenix; Pinnaroo—L. C. Fischer; Clare—A. H. Rogers, F. W. Knappstein, A. G. Coombs, W. R. G. Harmer, C. A. Wilcox, M. P. Vandborg, G. Smith, J. C. Dux, M. Lee, A. Lee, C. Neat, K. Russell, Les. Jarman, T. Gill, E. O'Shaughnessy, R. Smith, M. Fudge, V. Crawford, R. Fuller, M. Rogers, A. R. Ninnes; Berri—H. A. Fewster, H. M. Perkins, Robt. Curran, F. W. Seekamp; Eudunda—L. T. Duldig, A. R. Schultz, F. C. Lindner; Kapinnie—C. LeKraft, E. W. Franks; Appila—F. Winter; Tantanoola—Thos. Howe; Renmark—Robt. Edmeades, L. P. Johncock, W. E. Meier; Bowhill—A. Cockshell, A. Otto, E. B. Rohrlach; Tintinara—J. B. Lewis, Philip Champion, Ross C. Harvey; Millicent—A. C. Shepherd; Gladstone Women's—Mrs. Campbell, Mrs. Venning; Kyhybolite—A. Greive, S. B. Castine, W. Sanders, M. Crunkhorn; Netherton—A. C. R. Eglinton; Boolgun—Herbert Castle; Beetaloo Valley—H. T. Head, F. Bartrum, A. T. Brown; Black Springs—P. Copestake; Kulyan—R. E. R. Lang; Penwortham—Blackett, Chynoweth; Pinkawillinie—W. F. Freeth, A. Heath, H. Heath, R. Ballantyne, W. Vivian, Warc; Palabie—G. M. Mayhew, L. Wilks, H. Luestner, A. E. Place; Blyth—Wm. Brereton, P. Tonkin; Mount Barker—R. F. Edwards, K. M. Bowen; Pinnaroo—Geo. Lloyd; Pinnaroo Women's—Mrs. N. O'Loughlin; Kanni—J. Platten, J. Platten, jun., V. T. Platten, R. Picard, G. Gregory, E. Schultz; Miltalie—J. T. Forth; Riverton—E. Travers, A. O. Thomas; Brinkworth—E. R. Ottens; Truro—E. B. Schilling, P. S. Klemm, O. Habel, H. Habel, M. Habel; Balaklava—A. S. Smart; Lyndoch—J. C. Daly; Hartley—Wm. Yeates; Laura—H. F. Klemm, A. Klemm; Nelshaby—G. Verwort, J. H. Franks, S. Turner; Currency Creek—W. A. Robinson; Talia—W. Thomson, F. P. Thomson, B. Hardy, R. Lewis, M. Cameron; Nurrkimpita—Jas. Davies, Edwin Gum; Wilkawatt Women's—Mrs. H. L. Billing; Bute—E. W. Bettess, J. A. Otte; Rapid Bay—Frank Macrow, R. Hooper; Keith—A. W. Dellow, C. D. Ellis; Coorabie—E. H. Attick, E. H. Johns, T. F. Gurney, Roy Gurney; Alawoona—A. G. Pengilly, L. Smith; Yandiah, E. R. Speed; Millendilla—F. Bartel; Nelshaby Women's—Mrs. W. E. Martens, Mrs. L. C. Roberts, Mrs. R. L. Smith, Mrs. J. Turner, Mrs. W. Lock, Mrs. H. Burford; Kapinnie—G. R. Rieman.

Number of Branches, 297; total number of members, 8,216.

## DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co., LIMITED, reported on August 1st, 1930:—

**BUTTER.**—The outlook for the dairying industry has shown a vast improvement during the past few weeks, for, owing to the good general rains that we received throughout July, the pastures have come along rapidly, and the importation of butter from the Eastern States has ceased. The growing conditions have been almost ideal, and consequently with production coming along rapidly there should shortly be a surplus of butter for export. Values have eased during the last week or two, and with London markets weak further easings must take place to export parity, and rates would then steady according to the values obtainable by overseas trade. Meanwhile steadily increasing supplies of cream and butter are coming to hand, and the quality is of a high standard. Choiceest creamery fresh butter in prints, 1s. 9d. per lb.; second and third grades, 1s. 6d. (these prices are subject to the stabilisation levies); best separators, 1s. 5d. to 1s. 6d.; well-conditioned store and collectors, 1s. 2½d. to 1s. 3½d.

**EGGS.**—As usual at this time of the year, quantities are showing an increase each week, and as the surplus is now a considerable one, it will be taken up by pulpers, and exporters values have come back. However, it is now expected that pulpers and picklers will be operating freely, so that consignments will be kept clear. Ordinary country eggs, hen 8d. per dozen, duck 9d. per dozen; selected, tested, and infertile higher.

**CHEESE.**—The conditions in the South-East are good, and it is expected that the production of cheese will be greater than last season. So far consignments received have met with ready clearance to local and Western Australian buyers, and the market is steady. New makes, large to loaf, 9½d. to 10½d. per lb. Semi-matured and matured, to 1s. 1d. per lb.

**ALMONDS.**—After a period of dullness in the market, there was an improved demand in this State for all classes of almonds, and stocks have now been considerably reduced. Kernels also have been meeting with better demand, so that the quantities held are only light. Brandis, 7½d. to 8½d.; mixed softshells, 6½d. to 7d.; hardshells, 4d.; kernels, 1s. 7½d. per lb.

**HONEY.**—This commodity has not been selling nearly so freely this year as in other seasons, and is due to the fact that interstate buyers have been carrying stocks from the previous year, and have, therefore, not needed the usual quantities from South Australia. Sales have been limited during the past month or two to prime clear extracted, and lower grade lines are neglected. Prime clear extracted in liquid condition, 4½d. to 5d.; best quality candied lots, 4½d. to 4¾d. per lb.; second grade honey, 3d. to 3½d. per lb.

**BEESEX.**—No alteration to report; 1s. 5d. to 1s. 5½d. per lb., according to quality.

**BACON.**—There are ample stocks of bacon held by all curers at present, as supplies of live hogs to the markets have been good, although the turnover is being steadily maintained in bacon, the demand for hams is somewhat slow. Best local sides, 11½d. to 12½d.; best local factory-cured middles, 1s. to 1s. 1d.; large, 10d.; local rolls, 9½d. to 10½d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 5d.; local hams, 1s. to 1s. 1d.; "Sugar Cane" brand lard, in packets, 11d., in bulk, 10d. per lb.; local lard, 9d. per lb. in prints.

**LIVE POULTRY.**—The demand for all classes of poultry has maintained better than was expected, and although our sales each week have been well supplied with consignments from the country, and also suburban yards, yet the demand has been sufficient to absorb all lots at satisfactory prices. The special sales of purebred birds held during the month have also met with acceptance, both to buyers and sellers, and the rates obtained were good and commensurate with the standard of the birds. We advise consigning. Crates loaned on application. The following prices ruled at Friday's sale:—Prime roosters, 4s. 6d. to 5s. 9d.; nice-conditioned cockerels, 3s. 6d. to 4s. 3d.; fair-conditioned cockerels, 2s. 6d. to 3s.; chickens lower. Heavy weight hens, 3s. 3d. to 4s. 6d.; medium hens, 2s. 6d. to 3s. 1d.; light hens, 2s. to 2s. 4d.; couple of pens of weedy sorts lower. Geese, 4s. 6d. to 6s. 9d.; prime Muscovy drakes, 3s. 9d. to 5s.; ducks, good conditioned, 2s. 9d. to 3s. 5d.; ducks, fair condition, 2s. 3d. to 2s. 7d.; ducklings lower. Turkeys, good to prime condition, 9½d. to 11½d. per lb. live weight; turkeys, fair condition, 7½d. to 8½d. per lb. live weight; turkeys, fattening sorts lower. Pigeons, 7d. each.

**POTATOES.**—Best South-Easterns, 8s. 6d. per cwt.

**ONIONS.**—Best brown, 6s. per cwt.

A.M. Annual meeting.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

#### SOUTH-EAST DISTRICT.

##### ALLANDALE EAST.

June 6th.—Present: Nine members.

The meeting took the form of a Question Box. Mr. Laslett asked which fodder produced the most milk—hay or chaff. He had tried both, and found that his cows, when fed on chaff in boxes, wasted a good deal, and bolted the rest. He had fed them on long hay, Imbros Island oats, and though there was a certain amount of waste, the cows gave as much milk, and, taking into consideration the cost of cutting the hay into chaff, he thought it was just as well to feed the hay in the sheaf. Mr. Butler said that cows ate chaff greedily as a rule, but on account of their ruminating habits they still made full use of the fodder. It would take some experimenting to decide the question. "Is it possible to show a profit by top dressing land this year?" Mr. Parish said that land top dressed would carry an extra sheep per acre. The price of sheep and wool was low this year, but he still thought it would pay to top dress. The Chairman was of the same opinion. He had used more super this year than usual, which showed that he was willing to back his opinion with his cash. His pastures were better this year, especially a paddock of subterranean clover. This clover, once established and top dressed, would nearly double the carrying capacity of the land. Mr. Griffin favored rye grass, even in summer. After a shower of rain it would sprout, and provide a green bite when all else was dry. Mr. Kieselbach failed to see how top dressing would show a profit in a year like the present. It was said that the weight of wool was increased, but it would take an extra fleece of wool to pay for 1cwt. of super per acre. He had not practised top dressing, yet he had just sold some fat lambs for a good figure. Another questioner asked if it would pay to shear crossbred sheep twice a year. Mr. Earl, who asked the question, said that at crutching time this year the crossbreds were showing a fine staple of wool. He thought that if sheep were shorn in September and again about March, before the end of autumn, no injury should result to the sheep, and two wool cheques would be very acceptable in these lean times. It was stated that wool shorn in March would be light, but as wool was sold on a clean-scoured basis, the absence of yolk would be no detriment. Members seemed to agree that one fleece a year was all that could be expected. "In what months of the year are vetches injurious to stock, and if they affect sheep, in what way?" Mr. Laslett said that, as a rule, sheep would not eat enough of this

## SENTIMENT OR SECURITY?

**SENTIMENT** sometimes dominates the mind of the Testator when choosing an Executor, causing him to overlook that more important essential—**SECURITY**.

While the value of friendship to the family should not be under-rated, **READINESS** on the part of a friend or relative to serve as an Executor should not be mistaken for **ABILITY** to undertake these exacting duties.

Appointing a friend for sentimental reasons, regardless of his qualifications, frequently ends in disaster. **SECURITY** is the first essential, and is obtainable by appointing—

TRUSTEE AND EXECUTOR COMPANY LIMITED,  
35, CURRIE STREET, ADELAIDE.

weed to do them harm, provided there was grass in the paddock where they were running. Mr. Yateman said that if cattle or horses were put in a paddock where vetches were in seed, once they took to eating the seed they would keep on eating them, with very harmful effects. It was a good thing to bleed an animal that was so affected; in fact, he thought it was the only cure. Mr. Earl said his sheep were running in a paddock where there was a lot of vetch, but they did not eat it so long as there was other feed about. Mr. Butler said he had a small patch of it in his paddock, and he tried to dig it out, but the roots were tough and penetrated the soil to a great depth. It was suggested that the small patch might be covered with seaweed; this would kill all vegetation for a year or so, but after that time grass would grow again. The vetch plants flowered in September and October, and bore seed immediately afterwards.

#### COONAWARRA.

Meeting held June 4th. Present: Nine members. A discussion on "Pruning Apricot Trees" took place.

### MIDDLE-NORTH DISTRICT.

#### (PETERBOROUGH TO FARRELL'S FLAT.)

BELALIE NORTH (Average annual rainfall, 17.95in.).

June 5th.—Present: 14 members and visitors.

During the afternoon a pruning demonstration was given by Mr. J. B. Harris (District Horticultural Instructor). The evening meeting took the form of a social. Items were rendered by Miss E. Cummings, Messrs. W. J. Cummings, J. B. Harris, and E. J. Carmichael. Mr. H. C. Pritchard (General Secretary, Agricultural Bureau) addressed the meeting on topics connected with the Bureau. He then presented trophies won in the Seed Wheat Competition to Mr. F. L. Carmichael, first; Mr. A. D. Bray, second; and Champion (presented by Superphosphate Association) to Mr. F. L. Carmichael. Mr. Pritchard then presented Life Membership Certificates to Messrs. W. Cummings, sen., and A. H. Warner. The President then presented Mr. W. Cummings with a silver inkstand, suitably engraved, on behalf of the Branch in appreciation of his services for 19 years as Secretary.

BELALIE WOMEN'S (Average annual rainfall, 17.95in.).

Mrs. Moore presided over an attendance of 15 members, at the meeting of June 4th, which was held at Mrs. Haskard's homestead, when a Rose Pruning Demonstration was given by Mr. J. B. Harris (District Horticultural Instructor). On June 13th 12 members attended the annual meeting of the Gladstone Women's Branch.

#### EVERARD EAST.

The annual meeting was held on June 14th, and was attended by 11 members. The Hon. Secretary (Mr. F. Hughes) presented the annual report, and officers were elected for the ensuing year.

KOOLUNGA (Average annual rainfall, 15.61in.).

June 10th.—Present: Nine members.

Mr. A. H. Buchanan read a paper dealing with "Poultry," in the course of which he stated that farmers would have to take more trouble and care in selection of stock, or they would probably find it difficult to obtain a market for eggs. Referring to the grading of eggs, he said both the Red Comb Egg Association and the National Egg Company Ltd. were of great benefit to the suburban poultry keepers, inasmuch as the difference in price was as much as 10d. per dozen above the market. It seemed almost impossible for ordinary farmers to join such associations, because they could not comply with the regulations of housing and feeding and general equipment. The association also had a tendency to lower the prices of grades sold by farmers, which during the summer were not always f.a.q. The stock on most farms was so mixed and inbred that they deteriorated in size and health. He considered it far better to keep 100 young fowls and look after them well than to keep twice the number and half-starve them. In order to keep them young and up to the mark it was necessary to spend a lot of time in ringing their legs and to keep on culling out any that appeared to be unprofitable. Unless they were rung or marked, one never knew their age or when to put them out. For a farm flock, the White Leghorn and Black Orpingtons were very suitable breeds. Although the blacks did not lay so continuously, they laid when eggs were a good price, viz., April, May, and June. In order to keep the flock up to whatever number one could look after, one should rear about that number of chicks each year,

because 50 per cent. were generally roosters, and it was necessary to allow for deaths. The day-old chick business appealed to the farmer, because in getting the chicks already hatched the trouble seemed to be over, but it was not so. The advantages over hen hatching were that all the trouble came at once in looking after them, and not so many coops and pens were needed as with the hens, but unless procured from a reliable person, by getting them, say, in July, one would probably get a fair percentage from pullets' eggs, which might be very small and hard to rear, because the older hens did not lay until later. Anyone breeding chicks from their own hens had a fair idea as to the class of egg they would produce, and by grading the best eggs of standard weight there would be an improvement in the progeny. Where hatched with the incubator, the chicks were healthy, and did not get any disease from the hens, such as scaly leg, to which the heavy breeds seemed to be very subject, nor head lice, which was responsible for a large percentage of deaths in chicks with the hens. On examination with a magnifying glass of a chicken affected with head lice, one would find scores of very small lice, which appeared to be standing on the head and burrowing into the skull. If left, and the chick did not die, the lice changed to the amber-colored lice found later around the vent and tail feathers. When that was the case the chicks were worried right from the start, and consequently lost their vitality, and were more subject to colds and roup. The tick was largely responsible for losses during the summer, such as cholera and diarrhoea, caused by poison inserted into the body from the tick bites. The droppings during the night would act as a guide to the bird's health. If light green and whitish, it indicated cholera, and if colored throughout with pale pink and meat-like substance it indicated round worms or diarrhoea, especially in half-grown chicks, which became pale and lost feathers. There was also the gape worm, a Y-shaped or forked worm of about  $\frac{1}{16}$  in. to  $\frac{1}{8}$  in. in length. They attached themselves to the mucous membranes of the windpipe and sucked the blood. The bird continually opened its mouth and gasped for breath. A feather dipped in turpentine inserted in the windpipe and turned round would remove some of the worms, or sulphur blown down the throat would help to dislodge them. *Housing.*—In housing poultry there were three essentials—face the east so that the morning sun shone right in, thereby purifying the air and at the same time helping to keep in check vermin which bred rapidly in dark, ill-ventilated houses. The north, south, and west of the house should be wind proof, because nearly all cold weather and rain came from those quarters. (2) The house should have a good roof to keep the rain from soaking through and causing dampness under the birds; and (3) the floor should be higher than the surrounding ground to keep the floor dry. To ensure good ventilation it was a good plan to leave a space between the back wall and the roof. Houses should be kept as clean as possible at all times. In feeding laying hens, wet mash should be fed in the mornings to obtain the best results. He used bran and pollard in equal parts by measure, the bran being scalded and allowed to swell, and then sufficient pollard added to make it dry enough to stay in the mould of the hand. During winter months 1 lb. of meatmeal and a little poultry spice added would be beneficial. As much greenfeed as one could give would help during summer.

---

## LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

BRINKWORTH (Average annual rainfall, 16.01 in.).

June 9th.—Present: 20 members.

The matter of awarding a prize for the competitor securing highest number of points over a period of years in the local Seed Wheat Competition was discussed and referred to a committee for further consideration. The following paper, "Lowering Cost of Production with the Diesel Tractor," was read by Mr. B. Ottens. An animated discussion ensued:—"During the past few years it has been the aim of the Australian wheatgrower to increase wheat production and produce it at less cost. Owing to adverse seasons which have existed practically all over Australia during the last three or four years, farmers have found it impossible to produce more wheat, consequently their attention has been forced to cutting their production costs. Thousands of farmers throughout Australia have changed from horse power to motor power on their farms, and after having worked the tractors for several years, are fully convinced that tractors will work as cheaply, or, in most instances, much more cheaply than horses. Nevertheless, the cost of producing a crop of wheat is still too high. No doubt many farmers will say, 'We know it is, but how can we lower it?' One way to do so is to use a Diesel or semi-Diesel engine tractor, instead of horses, or a magneto and carburettor-fitted kerosine tractor. After having perused several dozen papers written on tractors or power farming which appeared in the *Journal of Agriculture* from time to time, I

find that the cost of seeding with a kerosine tractor, for fuel, oil, petrol, and grease, ranges from 10½d. to 1s. per acre, averaging 11d. per acre. After having worked a crude oil Diesel tractor for four seasons' seeding, and kept an accurate daily account of same, I will endeavor to show that a Diesel engined tractor will cut 11d. per acre in half. Four years' seeding with a 20 hoe combine and a set of light harrows attached are as follows:—Area, 1,968 acres; time 567 hours; 418galls. crude oil at 11d. per gallon, £19 3s. 2d.; 151galls kerosine at 1s. 3d. per gall, £9 8s. 9d.; 62galls. oil (engine and gearbox), at 5s. 3d. per gall., £6 15s. 6d.; grease at 1½d. per day, 56 days, 5s. 5d.; ignition fuses for starting, 7s. 2d.; total, £45 10s. This works out at 5½d. per acre, or 1s. 7d. per hour. (Adelaide prices would be over ½d. an acre less). As 5½d. is just half of 11d., the cost with a kerosine tractor would be £91, or a saving of £45 10s. for the Diesel tractor. Assuming that a farmer ploughs, harrows twice, cultivates twice, sows and reaps 480 acres per year, it will take him approximately 850 hours to do so, with a 15-30 horsepower tractor. As the Diesel motor saves 1s. 7d. per hour in 850 hours, it would mean a saving of £67 6s. per annum. Again, assuming that a tractor lasts for eight years, the Diesel tractor would save £67 6s. per year, and, adding compound interest at the rate of 6 per cent. on the first £67 6s., and each £67 6s. until the eighth year, it would mean a saving of £625 15s., or, in other words, over £100 more than the price of a new tractor. The saving in fuel and oil are not the only ways a Diesel engine cuts down costs, however, for there is also the replacing of spare parts to be considered. The total cost for engine replacements for three years' ploughing, cultivating, seeding, and reaping (no harrowing), covering an area of 4,183 acres, does not exceed £19 10s., or £6 10s. per annum. After this sum was spent, the motor was practically like new, because the main wearing parts had been replaced: that is, pistons, cylinder barrels, and rings. Another great feature of the crude oil Diesel tractor is its extraordinary reserve power and simplicity of construction, doing away with the trickiest part of most motors, namely, the magneto and spark plugs, also the carburettor. Even the valves, push rods, rocker arms, &c., are eliminated in the semi-Diesel. Perhaps some farmers say, 'Yes; they are noted for economy and durability, but are they reliable?' During the three years I have only lost one day's work owing to the breakage of a small part. Nowhere is reliability of such great importance as in aeroplanes, where pilot and passengers' lives depend upon reliability, and I think the fact that to-day there are huge air-liners built which depend solely on Diesel crude oil engines, speaks for itself."

## YORKE PENINSULA DISTRICT.

(TO BUTE.)

KILKERRAN.

May 13th.—Present: 14 members and five visitors.

Mr. A. Sawade read a paper, "Farm Finance." Mr. Sawade said that because South Australia was a State which depended for its well-being almost wholly upon rural production, it naturally followed that the prosperity or otherwise of the rural producer would be reflected in the State as a whole. Some persons would no doubt say that drought conditions, prevailing during the past three or four years, combined with the falling prices of saleable produce, had been largely to blame for the farmers' difficulties. Nevertheless, Yorke Peninsula had not been hit so very severely by drought. In a few instances, yields had been slightly below the average, but in others they had been well above normal. Therefore, so far as their part of the State was concerned, they must look elsewhere for the cause, such as in the high cost of living, and in the high capitalisation of property. The economic factors that dominate the position might be grouped under two headings, namely:—(1) Mean cost of production; and (2) current prices offering for rural produce concerned. Over the latter, unfortunately, the producer had very little control. With regard to the former—costs of production—it could be said that while the farmer generally had an uneasy feeling of their immediate effects, he was rarely, if ever, able to define them with any degree of accuracy. Moreover, as such costs always varied from holding to holding, and from season to season, the value of any attempt to determine mean costs would largely depend on the number of units under observation, and upon the number of seasons over which the inquiry extended. During the past few years enormous prices had been realised for land in their district. It should be remembered that the mere fact of finding capital, whether personal or borrowed, to purchase and stock a farm was not the end of the story. That capital had to earn interest, which became the property of the owner if personal, or must be paid to his creditors, if borrowed. On a farm there was only one source from which interest could come, namely, the revenue of farm undertakings. It followed that net profits could only be claimed after interest claims on capital invested

had been fully satisfied. As an example, he took the case of a small farm of 600 acres, and assumed that the price paid was £30 per acre, that two-thirds of the farm would be cropped annually, and the remaining third fallowed, and that the area under crop would be half wheat and half barley. If wheat averaged 30bush. per acre at a price of 4s. and barley averaged 25bush. per acre and returned 2s. per bushel, with the invested capital at 5 per cent. it would give the following results:—Income—Wheat, 200 acres at 30bush. at 4s., £1,200; barley, 200 acres at 25bush. at 2s., £500; total income, £1,700. Expenses—Interest, 600 acres, £30, at 5 per cent., £900; interest farm plant, £1,500 at 10 per cent., £150; interest permanent improvements, £2,400 at 2½ per cent., £60; cornsacks, 11,000 at 9d., £137 5s.; kerosine and oil, 12 months' supply, £152 15s.; super, 20 tons at £5, £100; total expenses, £1,500; total income over expenses, £200. An animated discussion followed.

### WESTERN DISTRICT.

#### LAURA BAY.

Meeting held June 8th at Mr. W. W. Bowell's residence. Present: 11 members. An article, "The Blowfly Pest," was read by Mr. A. Dixon. This subject proved of timely interest. The blowfly is causing considerable trouble in this district.

#### MOUNT HOPE.

Meeting held June 10th. Present: Mr. T. Speed (Chairman) and 11 members. An instructive paper, "Stimulating Interest in the Work of the Agricultural Bureau," was read by Mr. L. Myers.

#### MUDAMUCKLA.

Meeting held June 14th. Present: 12 members. Mr. L. Watson read a paper, "The Uses of a Motor Truck on the Farm," which aroused an interesting discussion.

#### PINKAWILLINIE.

The monthly meeting was held at Mr. T. Hudson's residence. Mr. A. Lienert presided over an attendance of nine members. An excellent paper, "The Depression in the Wheat Industry, Its Cause, and the Probable Cure," was read by Mr. B. Hudson.

#### ROBERTS AND VERRAN.

June 11th.—Present: Eight members.

INCREASING PRODUCTION ON THE FARM.—Mr. H. Smith read the following paper:—"The first essential is to adopt a definite system of farm management. See that the stock and plant are as up to date as possible so that work can be done easily and well at the right time. On most farms in this district old and new land have to be cultivated. Always have early fallow, and see that it is well worked, free from stumps, etc., so that a good seedbed can be prepared. All weeds should be kept down, for which purpose sheep can be used between cultivations, and they will also help to pack the ground. Fallow should be worked when summer rains fall to conserve moisture and to prepare a good seedbed. Many farmers start to prepare the land at seeding time, which results in considerable loss. It means loss of early rains, a late seeding, and a late start with next year's fallow. Secondly, if the ground is in good heart, good seed and varieties suited to the district are important. All seed should be graded. In

districts where the rainfall is from 12-14in., early and mid season varieties should be selected, and it is also well to sow oats on fallow so that a good hay cut can be obtained. A farm that can produce plenty of hay feed, &c., is usually one that is properly prepared, worked, and sown at the right time. Large implements are a great help in seeding operations; seed can be quickly sown after a good opening rain. Thirdly—Various classes of livestock are necessary to increase production. Only the best should be kept, and with all stock up to the standard there will never be any difficulty in selling any surplus animals." Discussing the paper, Mr. J. Pahl agreed that good methods and breeding combined with mixed farming were essential for increased production. Mr. S. Barber said it was essential to work the land as often as was possible. Mixed farming practices were essential. Sheep of the best suited breed should be kept, and good stock raised at all times. Mr. L. Gordon thought shallow working of land in this locality was essential. He worked his land with the rigid tyne implement in preference to the spring tyne. He advised raising crossbred lambs for mutton and freezing. Mr. C. Masters considered it was not necessary to work the land unless weeds appeared; much harm was done working loose soils too frequently.

#### WIRBULLA.

Meeting held May 8th. Present: Eight members. The Hon. Secretary read several items from the *Journal of Agriculture* dealing with seeding and depths of sowing, which brought forward a good discussion.

#### WUDINNA (Average annual rainfall, 13.68in.).

Meeting held May 7th. Present: 11 members. An instructive paper, "Farm Economy," was presented by Mr. A. Shephard. The meeting was held at the residence of Mr. W. Bartley. Supper was provided by the ladies.

#### YADNARIE (Average annual rainfall, 14.09in.).

Meeting held May 20th. Present: 14 members. Addresses were delivered by Messrs. E. L. Orchard and H. D. Adams, of the Department of Agriculture.

#### YANTANABIE.

May 1st.—Present: 17 members and three visitors.

The meeting took the form of a "Question Box." The following subjects were discussed:—"Which is the most suitable type of horse for the district?" Messrs. R. Hagett and F. Miller favored the Suffolk Punch sire, being fairly active, clean legged, and medium weight. "What is the best depth to sow in this district?" Members favored a 1in. seeding. "Is it advisable to harrow, and when?" Several speakers had found that the use of harrows after the wheat was up most advisable. Mr. H. Mathews reported having harrowed part of his crop twice. Weeds were destroyed in this way, and the crop returned 3bush. to the acre, whereas the crop not harrowed was not worth reaping. About three weeks after the crop appeared it should be harrowed. Mr. J. Karutz reported excellent results from this practice. Charlock was destroyed by the adoption of this plan.

### EASTERN DISTRICT.

#### (EAST OF MOUNT LOFTY RANGES.)

#### BRINKLEY.

Meeting held on June 11th. Present: 20 members and two visitors. The evening was devoted to a discussion of correspondence and local matters, also the annual social to be held on July 11th.

#### BROWNLOW.

May 7th.—Present: 16 members and five visitors.

THE HOME GARDEN.—Mr. C. Schiller read the following paper:—"The ground should be covered with 3in. or 4in. of old stable manure, and dusted with lime before being dug up from 6in. to 9in. deep. A good watering once or twice a week is best. The ground should be kept free from weeds and be loosened with a hand cultivator every three weeks. Liquid manure will be found of great benefit to the garden. Let the water stand 24 hours on the manure before applying it to the garden. Shorthorn carrot, Swedish Giant cabbage, Cauliflower Metropolitan, Drumhead lettuce, White Spine cucumber, Early Dwarf and Early Prolific tomatoes are some of the best varieties obtainable.

# THE IMPLEMENT CO.

## Offer a Complete Line of Harvesting Machinery

Don't risk a whole year's work when you can ensure against loss by getting light running, easily handled harvesting machinery on which you can always depend to harvest and market your crop. You will find in the Implement Co. line the finest materials and workmanship—and, what's best of all, years of satisfactory service.

**HORWOOD-BAGSHAW  
"GASTON" HEADER.**

The simplest, easiest running, and most effective Reaper Thresher in Australia. Sizes, 8ft. and 10ft. cut. This machine has fully earned its name—"The Better Built Header."

**HORWOOD-BAGSHAW  
"ILLMAN" STRIPPER.**

The Horwood-Bagshaw "Illman" Stripper is the result of many years' close attention to the requirements of Mallee Farmers, and we are confident in offering this machine to fill the demands of the most exacting user. Made in 8-ft., 9-ft., and 10-ft. sizes.

~~~~~  
Write for catalogs and prices of the above, also "Horwood-Bagshaw" Winnowers, "Austral" Binders, "Horwood-Bagshaw" Wheat Elevators, "Frost & Wood" Hay Rakes and Hay Balers.

# THE IMPLEMENT COMPANY

**BANK AND BLYTH STREETS, ADELAIDE.**

**TULKINEARA.**

Meeting held June 11th. Present: 11 members and five visitors. Mr. A. H. Robin, B.V.Sc. (Government Veterinary Officer), addressed the meeting on the subject, "Ailments of Cows." Numerous questions were answered by Mr. Robin.

**WILKAWATT WOMEN'S** (Average annual rainfall, 16in. to 17in.).

The meeting of April 15th took the form of a social afternoon held at Mrs. Koch's residence. Items of interest were read to the members by Mrs. Koch. Afternoon tea was then served and a visit was made to the garden.

**YURGO.**

Meeting held April 30th. Present: 10 members. The meeting took the form of a "Question Box." Several questions were asked, each being followed by an interesting discussion.

**YURGO.**

Meeting held June 5th. Present: Nine members and two visitors. Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address relating to diseases in wheat crops. An instructive discussion followed.

**SOUTH AND HILLS DISTRICT.****PORT ELLIOT** (Average annual rainfall, 20.05in.).

May 17th.—Present: 18 members and two visitors.

**CONVERTING SCRUB COUNTRY INTO PASTURE LAND.**—The following paper was read by Mr. W. Drummond:—"There are various types of scrub country, but for the purposes of this paper our attention can be confined to three, namely—big timber, timber too large for rollers, and rollable scrub. The first mentioned is naturally the more slowly developed, because more work is entailed in bringing about the desired result. Probably the easiest and most effective way of handling very big timber is by cutting a frill with an axe into the sap-wood and immediately pouring in an arsenic solution. Timber treated in this manner dies gradually, commencing at the extremities of the lower limbs, and working inwards until eventually the top of the tree is reached. One advantage of this work is the lack of shoots. In country where big timber is not too thick this method should prove very successful. Country that has timber too large for the roller must be axed, and the only method that is to be considered at the outset is mullenising, i.e., to cut level with or, if possible, below the ground. It would probably pay to have the wood cut up into lengths ready to be handled as firewood. Timber handled in this way takes about 12 months to dry sufficiently to be used for firewood, and before the wood is cleared off, shoots are very vigorous. From the moment the wood is carted this country should be treated in the same manner as unhandled scrub that is readily rolled, apart from shoots, and for the sake of eradicating undergrowth. This course will be found desirable. From now on I propose to give both types of country the same treatment. In both cases, a good rolling well done is worth infinitely more than a badly-done job. The best time to roll is as soon after winter as possible, so that the roots of the scrub will receive a check at the time of rolling, and also at the time of burning through the shoots from 1ft. to 2ft. in height. A good burn helps tremendously in clearing undergrowth, as well as saving a large amount of work in the clearing up prior to ploughing, and having a large influence on subsequent cropping. Yaccas are a rather difficult proposition. Our practice has been to use a cutter, and with this and the aid of a sledge hammer to shear them off level with the ground, after which it is a comparatively easy matter to cart them into heaps and burn them. The first cultivation should be a good one, and I prefer using a heavy cultivator to a disc plough. If a disc plough is used to do a good job it means that undue strain is imposed on the implement when negotiating stumps, and consequently breakages and worn-out parts are continually requiring replacements. My main objection to this machine is its inability to perform even work on the bed of the ploughing. Heavy cultivators are available that will take through a large quantity of rubbish, and at the same time bring all roots of undergrowth to the surface of the ground instead of burying it as in the case of a disc plough. The ground should be left as fallow before cropping, thereby enabling several workings to be performed. This would make for the surer method of destroying the undergrowth, and enhance the chance of a better return from the subsequent crop. It may be argued that the shoots will become a menace, but this is one of the best times to give the stumps a severe check. Knocking the shoots off the stump with as much bark as possible during the autumn months will give the stump a better check than a burn, for it severs all the eyes from which new shoots spring, thereby

## AGRICULTURAL VIEWS AND COMMENTS.

### Conferences.

Conferences of the Agricultural Bureau will be held as under:—

Murray Mallee, September 30th, at Alawoona (Secretary, Mr. B. L. Finey).

Eyre Peninsula (Eastern), October 6th, at Kimba (Secretary, Mr. M. Martin).

Eyre Peninsula, October 9th, at Wudinna (Secretary, Mr. C. A. Newbon). Altered from October 8th.

Non-irrigated Fruits Districts, November 4th, at Angaston (Secretary, Mr. K. Robinson).

Papers, questions, &c., for Conferences should be in the hands of the General Secretary, Agricultural Bureau, Adelaide, a fortnight before the respective dates stated above.

### Tobacco Growing.

Mr. W. J. Spafford (Deputy Director of Agriculture) states that in connection with the growing of tobacco in Australia, it must be remembered by anyone contemplating becoming a grower that air-cured leaf is not saleable, and so it is necessary for all producers to erect a flue-curing barn for the preparation of the leaf. As quality of the cured leaf is more important than quantity, the climate of the locality and the soil type must be carefully considered, because they play a great part towards the production of the required quality. Where the climate of a district is sufficiently favorable for the fermenting of good leaf, the usual difficulty is to find suitable soils, because it appears that in the Adelaide hills good color and fine texture can only be secured on soils so light in color that they are almost white, and then they should be resting on a yellowish clay about 2ft. from the surface. The land should be liberally fertilised with superphosphate, say, 3cwt. per acre, and some of the really light-colored and light-textured soils should also receive sulphate of potash and sulphate of ammonia. If sufficient rain does not fall in the summer to keep the plants growing strongly, just enough irrigation

*Close Skimming  
Easily Washed  
Self-Oiling*

*Japanned Finish  
Durably Built  
Increased Capacities*

In all six sizes of the McCormick-Deering Cream Separator, four high-grade ball bearings are used at points 1, 2, 3, and 4, shown above.

## *The Model of* **Easy-Running Efficiency**

It's the combination of ball bearings and positive, automatic oiling that makes the McCormick-Deering Cream Separator so easy to turn. Try the one on display at the McCormick-Deering agent's store and see for yourself how easily and quickly you can make the bowl run at separating speed.

Examine the scientifically designed discs that skim warm or cold milk with maximum butterfat recovery. And remember to notice how readily the glossy japanned finish wipes clean.

McCormick-Deering Ball-Bearing Cream Separators come in six capacities—from 35 to 150 gallons of milk per hour—a size for every herd. Catalogue on request.

water should be given to promote healthy growth. Too much irrigation leads to excessive rankness. The seed should be sown in seed boxes, and, preferably under glass, in September; transplanting will then be done in November. The spacing of the plants will depend on the soil in which they are grown; in the Angaston district they should be about 30in. apart in rows about 36in. apart. There is no one in this State who grows tobacco seedlings for sale, but some growers have a big surplus of plants each year, and they sell them at about £1 per 1,000.

---

#### **Wheats for Low Rainfall Districts.**

Mr. W. J. Spafford (Deputy Director of Agriculture), in reply to the question, "What are the names of the three newest varieties of wheat for drier districts," which was asked at the Conference of Upper North Branches of the Agricultural Bureau, said of proved wheats for dry districts there had been two prominent successes. Nabawa had been the outstanding wheat of the last 10 years for low rainfall conditions. It produced grain of a first-class quality and was resistant to flag smut. Next was Canberra, a variety which was earlier than Early Gluyas, but very susceptible to loose smut. Sultan was also a popular variety and now occupied sixth place on the list of important wheats grown in this State. Roseworthy College had recently bred a wheat "Sword" (Sultan x Ford) which had given better returns than any crossbred wheat raised at the College. In Western Australia two varieties in Noongaar and Merriden were proving themselves under light rainfall conditions.

---

#### **Wheat Mildew.**

The following inquiry has been received from the Elbow Hill Branch of the Agricultural Bureau:—"Several crops of wheat in this district are affected with a disease of some description. The plants affected have a loose, white, powdery substance adhering to the leaves and stem exactly the same as red rust attacks wheat." In reply, the Deputy Director of Agriculture (Mr. W. J. Spafford) says the disease referred to, in all probability, is wheat mildew. In some seasons this disease is fairly common in some portions of the State, but as a rule does not do much damage. It is most noticeable while the wheat plants are quite small, and as the season advances practically all signs of the disease disappear and to outward appearances the crop recovers, although the yield cannot possibly be as good as if the crop had not been affected. When the disease is prominent early in the season, feeding off the affected crop will help it considerably, as admitting sunlight and wind tend to kill the fungus.

---

#### **Flax Culture.**

The Tatiara Branch of the Agricultural Bureau, who sought information on flax culture, has been informed by Mr. W. J. Spafford (Deputy Director of Agriculture) that flax has been grown in many localities in South Australia at different times, and in the early days several mills for handling the fibre were operated, but during each period when interest in the crop was worked up, it was found that other crops were more profitable. The crop grows well anywhere in this State where the annual rainfall is 25in. or more on the average, but for the handling of the flax a plentiful water supply as well as good rainfall is essential.

---

#### **98 per cent. Super.**

At the Conference of Upper North Branches of the Agricultural Bureau the following question was asked, "Have the departmental officers had any experience with 98 per cent. super that is on the market, and would it pay to use same instead of the 45 per cent. as a saving in freight and handling?" Professor A. J. Perkins, in reply, said departmental experience showed that returns from 98 per cent. super corresponded to those secured from equivalent quantities of 45 per cent., i.e., 41lbs. of 98 per cent. super gave

(PATON)

as good returns as 90lbs. of 45 per cent. He was informed by sellers that Adelaide prices were as follows:—98 per cent. super, £11 15s. per ton; 45 per cent. super, £4 15s. per ton; rail freight to Orroroo, 15s. 6d. per ton. As an illustration, it would be supposed that a farmer put in 300 acres and used 90lbs. of 45 per cent. super per acre, 12.05 tons, which would cost him £57 4s. 9d. for this super. With 98 per cent. super he would need 5.53 tons at £11 5s. per ton, £62 4s. 5d., a difference of £4 19s. 6d. Freight on 12.05 tons of 45 per cent. at 15s. 6d. per ton equals £9 6s. 9d., and freight on 5.53 tons of 98 per cent. super at 15s. 6d. equals £4 5s. 9d.—less difference in costs of super, £4 19s. 6d.—a saving of 1s. 6d. Therefore, there would be a saving of 1s. 6d. only, plus freight and handling on the farm.

### Export Lambs.

Following an inquiry made by the Mount Compass Agricultural Bureau, Mr. W. J. Spafford (Deputy Director of Agriculture) states that the ideal lamb to send to English markets is one that has reached "primeness" whilst being suckled by its mother. In shape it should be short, with deep and broad brisket, and broad, flat back, rounded ribs, rounded rump, well filled between the hind legs, and have relatively short legs. Because it is usual in England to regard the meat from the black-faced breeds of sheep as being better quality than that from the white-faced breeds, the lambs exported should have black faces. The breeds of sheep used to produce ideal export lambs will depend on the natural conditions obtaining. Where the rainfall is heavy and lambs can be reared properly if dropped in the spring, probably the best lambs would be secured by mating Southdown rams with Border Leicester, English Leicester, or Romney Marsh ewes. Next in importance to Southdowns would be Shropshire rams for these conditions, and the ewes might be replaced by Corriedales or halfbreds bred from Merino ewes by one of the long-wool breeds. Where it is essential that the lambs be dropped in the autumn and winter, the ewes would be half-bred Border Leicester, English Leicester, or Lincoln or pure-bred Corriedales, and the rams used would be Southdowns.

### Planting Orange Trees to Minimise Wind Injuries.

A correspondent at Mannum states that he is planting 300 orange trees, and asks for the best plan to adopt in spacing the trees in order to reduce wind injuries to a minimum. The inquiry was submitted to the Chief Horticultural Instructor (Mr. G. Quinn), who suggests that the trees be planted on what is often called the "staggered" system, but is known to fruitgrowers as the septuple or hexagonal method. This method of allotment places the trees so that viewed diagonally the lines of trees run at an angle of 60° in every direction. For setting out a small area of reasonably even-surfaced land, all that is needed to peg it out accurately is to project a straight line along the outer edge of the headland—preferably along the highest side, if there is any slope on the land. Then take a wire—No. 10 galvanized is suitable—fix a fairly large ring on one end, and on the other fix a pointed stake. See that when the wire is stretched straight the distance from the outer edge of the ring to the centre of the pointed stake, i.e., at the point, is the distance apart the trees are to be planted. Measure with this the spaces on the base line, and drive a peg in at each position.

Then, starting at one end, drop the ring end of the wire over the first peg, draw it tightly, and describe an arc on the ground at what seems midway between the first and second pegs and where the second row is expected to be placed. Move the ring on to No. 2 peg and repeat the movement back over the same spot, and where this second arc intersects the first one is the exact position for a stake. Repeat this from each peg along the full length of the base line, then straighten up and firm this second line of stakes, and use them as a base line to project the next row, and so on across the field.

Two wires of the same length with a ring on each end can be used to define the tree positions. In that case, one end ring encircles adjacent pegs, and the other ends stretched until the rings overlap, which gives the position for the peg.

FORD CARS  
and TRUCKS  
are BRITISH  
EMPIRE  
PRODUCTS

# Hard work this!

## Ford trucks excel at difficult haulage

**CONVINCING** proof of the marked superiority of the Ford 30 cwt. Truck was given recently on particularly difficult road-making operations at Turton's Track, Beech Forest (Vic.)

After severe competitive tests, Ford 30 cwt. Trucks were selected by Contractor C. Snell for the work of carrying quarried stone up a precipitous, rough and winding track from a quarry hundreds of feet below the road.

So steep and rough was the zigzag track that, instead of curves, dead ends were planned, the trucks running forward to a corner, then "reversing" to the next—a test of driving skill as well as of security of brakes.

The Ford Trucks averaged 20 trips per day carrying over 1½ yards of stone per trip. The fact that many thousands of miles were accomplished without damage or strain proves positively the tremendous reserves of strength and power possessed by the new Ford Truck. Motors, chassis, gears, brakes, and bodies all stood the test magnificently.

"Per National Economy"

It is in work of this grueling nature—in achieving the apparently impossible—that the new Ford Truck has built its splendid reputation throughout Australia. And its proved economy is as remarkable as its proved performance.

Ford 30 cwt. Standard Dumpable Truck

What about your haulage work? Have you visited your nearest Ford Dealer and seen this remarkable Truck demonstrated—have you driven it yourself—or had your drivers handle it? If not, then do so now, for its unusual power, sturdiness and adaptability demand first hand knowledge in times when lower costs of haulage may mean the difference between profit and loss in your business.

R.C.30/

FORD MOTOR COMPANY OF AUSTRALIA PTY. LTD.

Mr. Quinn suggests, if the land be deep and good, the trees be placed 24ft. apart on this septuple or staggered system. This will give about 87 trees per acre. If the soil is not calculated to grow large trees, set them 22ft. apart septuple, which will take about 102 trees to cover each acre. The space devoted to the pegged-out headland is deducted from the plantable area.

If the trees are planted 24ft. apart on the square and, as suggested, a fifth tree is set in the centre of the square made by each four it will form what is known to fruitgrowers as the quincunx system of allotment. This interplanting system would give about 137 trees as against 75 where the trees are in squares of 24ft. each way. It would not only crowd the trees, but the cultivation lanes would be narrowed down to approximately 17ft. in two directions, and 12 in two others, which certainly allows insufficient room for the trees to expand and a cultivator to be used between them.

If you wish to try planting a wind shelter, why not try a closely-set hedge of common bamboo reeds. They could be set within 25ft. of the outside row of trees, and their roots do not spread long distances.

---

#### Stable Manure and Fruit Trees.

Replying to the Balhannah Branch of the Agricultural Bureau which asked, "What is the chemical action of stable manure on fruit trees?" the Chief Horticultural Instructor (Mr. Geo. Quinn) says it is claimed by authorities on agricultural chemistry that a ton of a pure sample of stable or horse manure, which has not been leached by water or rain or permitted to become excessively heated by fermentative action, and become what is known as "fire fanged," may contain as high as 17lbs. of nitrogen, 13lbs. of potash, 9lbs. of phosphoric acid, and 10lbs. of lime. The average sample of stable manure as handled and used here could not be expected to still retain these quantities, more particularly the nitrogen. The kind of food given the horses and the ages of the animals would also influence the quantities of these compounds found in the manure. As far as our knowledge extends, it is generally conceded that it is not so much the gain received from the direct addition to the land of these plant foods from the manure itself that benefits the trees or crops, but the indirect actions it has on the soil body. The mass of organic matter absorbs water and holds it, whilst in its slow decomposition it liberates heat, and facilitates the formation of carbonic and humic acids, which in turn assist in breaking down insoluble mineral compounds containing plant foods, but which ordinary soil moisture could not bring into solution. Its physical action on the soil renders it friable, open, and aerated. It appears to be the essential medium for securing greater bacterial activity in the soil. It is possible the results of this increased activity are the more direct cause of stimulating the growth of foliage, shoots, and fruits on our fruit trees than is the addition of the quota of the plant food elements mentioned above as being conveyed to the land in the manure itself.

---

#### Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of the following publications:—

"Cocoa: World Production and Trade," Report No. 27.

"Biological Control of Insect and Plant Pests," W. B. Thompson, Ph.D., D.Sc., Report No. 29.

"Canadian Fruit Shipments," Report No. 30.

"Production of Tung Oil in the Empire," Report No. 31.

The above are published by the Empire Marketing Board. Price, 1s. each net.

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

[Replies supplied by Government Veterinary Officers, Stock and Brands Department.]

"F. W. C.," Hawker, reports cow in milk for 12 months. Milk when scalded becomes curdled.

Reply—The condition may be due to the cow drying off, especially if the cow is well forward in calf. Try the following general treatment:—(1) Give drench of—Epsom salts, 1lb.; ginger, 4 tablespoonfuls; treacle, 1 cupful; warm water, 2 pints. (2) Subsequently feed on good quality feed—bran and chaff (damped), and mix in a handful of sterilised sweet ground bonemeal daily. (3) If green feed is available this will help to restore condition. Advise if condition gets worse.

"H. G. L&G.," Coomandook, asks cure for cows which develop symptoms of staggering gait and staring eyes, then go down, are blown, and ultimately die.

The symptoms point to the trouble being due to either of the following conditions:—  
1. Bloat. 2. Milk fever. 1. *Bloat*.—This is the name given to a condition due to the accumulation of gas in the paunch, and the symptoms vary according to the amount of gas present. Those described by you would occur when the animal is dangerously distended with gas and on the point of suffocation. Treatment must be given at once, and consists of puncturing the paunch (which lies on the left side) in the triangular space situated between the bottom of the spine of the loins, the point of the hip, and the last rib. This may be done by means of a sharp pocket knife, followed by the insertion of a sharpening steel, which is moved about in order to keep the paunch contents from blocking the aperture and preventing the escape of gas. Four tablespoonfuls of oil of turpentine if injected into the paunch through a small tube will also help to prevent further fermentation of contents. In earlier stages the following measures will reduce the gas:—(1) Dabbing a little tar on the nose to make animal use her tongue, which helps to bring up the gas. (2) Placing a gag of wood in the mouth for the same purpose. (3) Drenching with 4ozs. of turpentine (8 tablespoonfuls) in one pint of milk. *Prevention*.—Do not allow on clover or rank grass growth when wet with dew or rain or while animals are hungry. 2. *Milk Fever*.—Somewhat similar symptoms may appear, but are generally restricted to cattle which have calved recently, and usually appear within 48 hours after calving. In these cases the bloating appears after the animal is down and unable to rise, and is due to the accumulation of gas caused by absence of bowel movement. *Treatment*.—Place cow on her brisket and prop up by placing a bag of sand behind her shoulder. Then wash udder with a disinfectant solution, and dry. Then inject each quarter with air until it is firmly distended, and tie teats with tape, which should be removed two hours afterwards. Air inflation may be repeated in three hours' time, but cows affected generally respond to treatment within three hours. The inflation of the udder may be carried out (in the absence of a proper milk fever outfit) by means of a bicycle pump and the valve from a bicycle tube (which must be boiled before inserting into the teat), or the quill of a feather may be inserted after connecting with the bike pump. In a case of milk fever, never drench a cow until she is on her feet and able to drink, otherwise the drench will not be swallowed, but will find its way into the lungs and cause pneumonia.

"G. H. M.," Younghusband, asks treatment for horses that have become gorged with wheat.

Reply—Administer as soon as possible a solution of baking soda in water (4oz. to 2 pints of water), and three hours later give 1½ pints raw linseed oil as a drench. Repeat half the dose of soda solution six hours later and again the following day. Allow animals as much water as they will drink. If feet trouble develops, trim the feet by lowering the heels, and place the animal in a trench containing water or on the swamp.

"W. B. C.," Paskeville, has cow showing symptoms of a form of rheumatism of the hindquarters.

Reply—It is recommended that you feed every other day up to 3ozs. or 4ozs. of either superphosphate, raw rock phosphate, or sweet ground bonemeal, mixed in with damson feed. If not handfeeding, then mix any of the above with coarse salt in the

of two parts of mineral to one part salt, and put the mixture out in a box in a handy position where the cow can have free access to it. To increase palatability, if super or rock phosphate is used, it may be found necessary to add 10 per cent. molasses. Dilute this with half its quantity of water, and then mix well into the mixture of salt and mineral phosphate.

"E. D. B.," Mcgrhiny, asks treatment for cow with a 2½ in. wound following treatment for "bloat."

Reply—When you punctured the paunch you should have injected about 4ozs. of oil of turpentine by means of a rubber tube or hollow piece of metal piping, &c., into the paunch to prevent further fermentation. However, if you can do so, the wound should be sewn up, first the paunch wound and then the skin wound. It is quite possible that the wound may gradually heal, but more probable that a fistula may result, from which food would ooze. If you do not attempt to sew the wounds up, I would suggest placing the animal on dry feeds. If you could obtain 2ozs. of chloroform and mix it with a pint of water, and drench the cow with the mixture when she is tied and on the ground, it will render the animal "dopey," and the sewing could be carried out without the least trouble.

---

## ORCHARD NOTES FOR SOUTHERN DISTRICTS. SEPTEMBER, 1930.

---

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

---

During the two months ahead of us we may make or mar the output of the orchard for the season. The whole of the work is done with the hope that a good crop of high quality fruit may result. To ensure this it will be necessary to give the very best of attention to the spraying programme. There are probably many important jobs to do, but not any of them are of so great importance as to prevent, as far as possible, the destruction of fruit by fungus and insect pests. We must admit that the weather plays a considerable part in determining our success, and we must work to overcome adverse weather conditions. For the protection of apples and pears against scab use Lime Sulphur or Bordeaux Mixture, either wet or dry; if rain washes it off, it must be put on again as soon as rain ceases. The same applies when Bordeaux is used for curl leaf of peach and nectarine, and shothole of apricot and plum. The preventive must be on the spot when the spores start to grow, or they will get a hold and damage will result. Aphis on peach and cherry must be dealt with as soon as noticed, and it must be carefully looked for; Black Leaf 40 or Nicodust is the material to use, and it must be put on to the insects, and used as often as further broods show themselves.

There is every probability of codlin moth giving us a bad time this year, and a start should be made at once to check it; scrape off all loose bark and remove all rubbish from about the tree. Be ready to get a first treatment so soon as the fruit is formed; forget all the controversy about the calyx spray, and just do it, and do it thoroughly, and keep a good coat of arsenate of lead on the fruit for some weeks ahead. Watch the packing shed and prevent escape of moths.

Treat vines for oidium with dust of sulphur, and watch for downy mildew.

Watch for cutworm on nursery stocks; use arsenate of lead.

Plant citrus trees and see that they do not suffer from want of water.

Keep strawberry beds clean; use a little of dust of sulphur to prevent mildews.

Do any grafting required, using only wood from known clean, good-bearing trees; do this work on fine days only; moisture may stop a good union.

Cultivation will, of course, have been completed; use the harrows after showers, and so keep a good surface; destroy any weeds which may have escaped thus far.

Order fruit cases early and ensure delivery in due time. Dip any used cases in boiling water.

## THE VALUE OF THE AGRICULTURAL DEPARTMENT TO PRIMARY PRODUCERS.

[*An Address given at a Meeting of the Quorn Agricultural Bureau.*]

[By ARTHUR J. PERKINS, Director of Agriculture.]

### INTRODUCTORY.

The subject matter of my address has been suggested by the Quorn Branch of the Agricultural Bureau, and whilst I shall endeavor to do full justice to it, I want it to be understood that I have not altogether been a free agent in the matter. I realise, of course, that quite a variety of reasons might have been responsible for the selection of this subject, but for the purpose of this address I shall assume that the main reason has been the natural interest of a body of producers in the working of a Government Department in which they are closely concerned, and I propose dealing with my subject accordingly. In this connection I shall endeavor to show both what the Department has tried to do, and what its members believe it has succeeded in doing.

### FUNCTIONS OF A DEPARTMENT OF AGRICULTURE.

In the first place, if I were asked to define in the broadest way possible the functions of a Department of Agriculture, I should say that they consisted of official efforts to further the interests of the Rural Industries of the State with which it was connected, and from this viewpoint these functions admit of being grouped under the following headings:—

1. The study of Technical and Economic problems affecting Rural Production.
2. Education and Propaganda work.
3. Administration of special Acts affecting Rural Production.
4. Social work in relation to primary producers.

### HISTORICAL.

The existence of the South Australian Department of Agriculture may be said to date back to the early eighties, when Mr. J. D. Custance was appointed Professor of Agriculture for the State. Its record of work, therefore, extends over 40 to 50 years. Next steps in development were represented by the opening of the Roseworthy Agricultural College in 1885, and the foundation of the Agricultural Bureau in 1888, and subsequently by progressive appointments of specialists in the various branches of agriculture, the establishment of experimental farms and orchards, and the appointment of district Instructors. Personally, I have now been attached to the Department for a period of over 38 years, and am therefore in a position to give first-hand information as to the extent and scope of its work.

I have already stated that the promotion of the interests of the Rural Industries is the main function of an Agricultural Department, and it follows that if we wish to justify the existence of the Department we should at the very least be in a position to show that during the period of its existence these Industries have made material progress. In this connection, however, it should be borne in mind that bricks cannot be made without straw, and that such work as may have been done has been conditioned by the means made available from time to time. Earlier steps were painful enough, not only from the absence of pecuniary support, but also from the lack of sympathy, and at times open hostility of those whom it sought to help.

### PROGRESS OF RURAL INDUSTRIES IN SOUTH AUSTRALIA.

Before, therefore, entering upon any details of work that has been done by the Department, I propose examining briefly what progress has been registered by our Rural Industries during the existence of the Department. Towards this end, I have summarised available mean Statistical data for four successive decades, namely:—

|           |             |
|-----------|-------------|
| 1889-90   | to 1898-99. |
| 1899-1900 | to 1908-09. |
| 1909-10   | to 1918-19. |
| 1919-20   | to 1928-29. |

To the latter I have added actual figures for 1928-29, the last year for which completed figures are available. It should be recalled, however, that in so far as crop returns are concerned, the results of a single season cannot fairly be compared with those of a decade, as they must vary very considerably according to the character of the special season under consideration. The data in question are given in Tables I., II., and III.—

TABLE I.—*Mean Areas of Four Successive Decades in Contrast with 1928-29.*

|                          | 1889-90<br>to<br>1898-99.<br>Acres. | 1899-1900<br>to<br>1908-09.<br>Acres. | 1909-10<br>to<br>1918-19.<br>Acres. | 1919-20<br>to<br>1928-29.<br>Acres. | 1928-29.<br>Acres. |
|--------------------------|-------------------------------------|---------------------------------------|-------------------------------------|-------------------------------------|--------------------|
| Wheat .....              | 1,646,976                           | 1,766,668                             | 2,310,095                           | 2,547,090                           | 3,445,563          |

| Bare Fallow .....        | 576,600                             | 974,643                               | 1,428,513                           | 1,844,173                           | 2,199,231          |
| Total Area Cultivated .. | 2,686,420                           | 3,254,377                             | 4,588,698                           | 5,558,705                           | 6,937,920          |

*Last Three Decades and 1928-29 Expressed in Terms of First Decade taken as Unity.*

|                          |     |     |      |      |      |
|--------------------------|-----|-----|------|------|------|
| Wheat .....              | 1.0 | 1.1 | 1.4  | 1.6  | 2.1  |
| Hay .....                | 1.0 | 0.9 | 1.4  | 1.5  | 1.4  |
| Barley .....             | 1.0 | 1.7 | 5.1  | 13.9 | 16.7 |
| Oats .....               | 1.0 | 2.4 | 5.8  | 8.0  | 9.8  |
| Green Forage .....       | 1.0 | 2.3 | 17.4 | 42.1 | 74.2 |
| Vineyards .....          | 1.0 | 1.5 | 1.8  | 3.2  | 3.6  |
| Lucerne .....            | 1.0 | 2.0 | 2.0  | 5.1  | 7.3  |
| Orchards .....           | 1.0 | 1.7 | 2.4  | 3.0  | 2.9  |
| Pease .....              | 1.0 | 1.5 | 2.0  | 2.7  | 3.6  |
| Potatoes .....           | 1.0 | 1.3 | 1.0  | 0.7  | 0.7  |
| Other Crops .....        | 1.0 | 0.9 | 0.8  | 0.7  | 0.8  |
| Total Area under Crop .. | 1.0 | 1.1 | 1.5  | 1.8  | 2.2  |
| Sown Grasses .....       | 1.0 | 1.2 | 1.2  | 2.2  | 3.7  |
| Bare Fallow .....        | 1.0 | 1.7 | 2.5  | 3.2  | 3.8  |
| Total Area Cultivated .. | 1.0 | 1.2 | 1.7  | 2.1  | 2.6  |

Table I. deals exclusively with areas cultivated and in crop during the four decades and in 1928-29. This Table is divided into two parts the upper one of which gives actual mean areas under crop, &c., in each decade and in 1928-29, and the lower one the same areas represented by 1.0 for the first decade, and for the remaining decades.

and for 1928-29 in terms of those of the first decade taken as unity. This arrangement enables us to see at a glance what progress has been effected in each decade for any type of crop.

Inspection of the Table will show that the total area cultivated has progressed regularly from decade to decade. Starting with a mean of 2,686,000 acres in the first decade and closing with a mean of 5,559,000 acres in the fourth decade, and in 1928-29—the last year of the fourth decade—this figure rose to 6,938,000 acres. Reference to the lower half of the Table will show that in 1928-29 the area cultivated was more than two and a half times that of the mean corresponding area of the first decade. These figures speak for themselves.

The area under crop has made corresponding progress, opening at 2,089,000 acres and closing at 3,668,000 acres for the fourth decade, and 4,660,000 acres for 1928-29.

Taking individual crops, progress has been continuous from decade to decade for Wheat, Barley, Oats, Green Forage, Vineyards, and Pease.

There was a decline in the area cut for hay in the second decade and latterly in 1928-29. On the whole, in view of the almost complete replacement of light horses by motor cars and the encroachment of Tractors and Motor Vehicles on Draught Horses, it is remarkable that the area cut for hay should not have declined to an even greater extent.

The decline in the area under Lucerne in the third decade must be looked upon as purely temporary and accidental.

The recent decline in the area under Orchards is attributable to the economic crisis which Orchardists have had recently to face in view of the present inadequacy of overseas markets, whilst the persistent decline in the area sown to Potatoes is due to the apparent inability of local growers to compete adequately with Eastern producers.

The most marked relative increases in areas under crop have been registered for Green Forage, for which areas cut in the fourth decade were over 42 times greater than those cut in the first decade, and in 1928-29 over 74 times; Barley 14 and 17 times respectively for the same periods; Oats eight and 10 times; and Lucerne five and seven times.

Very remarkable, too, has been the progress achieved in the area treated as Bare Fallow, which from a little over half a million acres in the first decade rose to over 2,000,000 acres in 1928-29. Sown grasses, too, have made correspondingly satisfactory progress.

It will be admitted that these figures show very clear evidence of progress from the viewpoint of areas cultivated or under crop.

Let us next consider the question from the point of view of mean total production, data concerning which have been given in Table II.:

TABLE II.—Mean Rural Production of Four Successive Decades in Contrast with 1928-29.

|                 | 1889-90         | 1899-1900  | 1909-10    | 1919-20    | 1928-29.   |

Table II. sets out production figures from our chief rural industries on the same lines as those already adopted for Table I., namely, the upper portion of the Table gives actual mean values, whilst the lower portion expresses these values in terms of those of the first decade taken as unity.

At this stage I shall recall that the comparison of production returns of a single season with corresponding figures of preceding decades is always open to possible misconstruction because of seasonal vagaries, favorable or otherwise, which must necessarily characterise the single season. In the instance under consideration, the fact must be stressed that over the bulk of our agricultural areas the 1928-29 season was unusually unfavorable, and that production figures of this particular season carry a heavy handicap relatively to corresponding means of preceding decades. Nevertheless, notwithstanding these seasonal difficulties, the progress of seven out of the 18 production items indicated in the Table was continuous over the three decades, including the unfavorable 1928-29 closing season. Of these, the 1928-29 production of Barley was 26.5 times greater than that of the mean of the first decade; of Wine 16 times; of Currants 164.1 times; of Olive Oil six times; of Oranges 8.6 times; of wool 1.7 times; and of Honey 4.6 times.

On the other hand, eight of the Production items indicated showed continuous progress over the three decades, but declined slightly in 1928-29 under the influence of unfavorable seasonal conditions. Of these we may note that Wheat reached in the fourth decade 3.6 times the production of the first decade, but declined to 3.4 times in 1928-29; Oats reached 10.4 and declined to 10.2; for Hay corresponding figures were 2.2 and 1.7; for Apples 2.1 and 1.4; for Butter 3.7 and 3.1; and for Cheese 4.2 and 3.9.

Finally, the Production of Pease, Raisins, and Potatoes have been somewhat irregular over this period of 40 years. Pease in the third decade attained to twice the mean production of the first decade, but declined to 1.9 times in the fourth and to 1.8 in 1928-29. Raisins were below the mean production of the first decade in all three succeeding decades, but rose to 1.8 in 1928-29. The latter fact is due to the comparatively recent development of the Sultana industry. Potatoes rose slightly in the second and third decades, but declined in the fourth, and still more in 1928-29. This unsatisfactory position is due in part to the successful competition of Eastern Potatoes, which local growers should be able to overcome.

On the whole, progress in rural production has been continuous and satisfactory during these 40 years, and particularly so in the matter of Currants, Barley, Wine, Oats, and Oranges.

In Table III. have been summarised data relating to Live Stock, Fertilisers, and Mean Crop Yields:—

TABLE III.—Additional Statistical Data of Periods under Consideration.

| Barley .....                                                                            | 1.0                       | 1.4                         | 1.4                       | 1.5                       | 1.6       |
| Oats .....                                                                              | 1.0                       | 1.8                         | 1.4                       | 1.3                       | 1.0       |
| Pease .....                                                                             | 1.0                       | 1.2                         | 1.0                       | 0.7                       | 0.5       |
| Hay .....                                                                               | 1.0                       | 1.4                         | 1.5                       | 1.5                       | 1.2       |
| Potatoes .....                                                                          | 1.0                       | 0.9                         | 1.0                       | 1.2                       | 1.0       |

It will be noted that, whilst Horses increased in numbers in the second and third decades, they decreased very appreciably in the fourth, and particularly in 1928-29, notwithstanding the fact that relatively to the third decade the area under cultivation in the fourth decade increased by 970,000. acres, and relatively to the fourth decade by 1,379,000 acres in 1928-29. This decline is attributable mainly to the general extension of motor vehicles and tractors. Dairy Cattle made progress in the three decades, but declined in 1928-29, whilst the progress of Sheep was continuous throughout. Pigs, on the other hand, have been more or less stationary owing to lack of adequate overseas market facilities.

The progress in the use of artificial fertilisers have been very striking, attaining in 1928-29 to 103.8 times the mean quantities used in the first decade. Similarly, in the same season the area dressed with fertilisers rose to 114.4 times the mean area so treated in the first decade.

It would not be fair to compare mean crop yields of a single season with the corresponding means of decades. I shall therefore content myself with saying that, with the exception of Pease, all crops have shown improved mean yields throughout the four decades.

I believe that I have succeeded in showing that over a period of 40 successive years the progress achieved in our rural industries has been highly creditable to all those concerned, but what is of even greater significance is that production from the areas

concerned has increased at an even greater rate than the expansion in territory occupied. Nor should it be forgotten that over recent decades new areas brought under the plough have been on the whole less fertile and under less favorable rainfall conditions than older settled areas, and that for many years they have carried crops only partially reclaimed from scrub. In these circumstances, crops from the more recently settled areas must have had a reducing rather than an improving influence on mean State yields. It follows therefore that the actually progressive improvement in mean State yields is all the more meritorious.

#### RELATIONSHIP OF THE DEPARTMENT OF AGRICULTURE TO RURAL PROGRESS.

I have already stated that to all intents and purposes the period of 40 years under consideration coincides with the existence of the Department of Agriculture in this State. I do not, however, wish to take credit where credit is not due, and recognise freely that the ultimate factors behind whatever progress may have been achieved have been the energy and enterprise of the rural community. But it is easy to imagine that all this energy and enterprise might have been headed in a wrong direction and wasted itself in more or less futile effort. I suggest, in this connection, that in fulfilment of its normal role the Department of Agriculture studied those facts which appeared to make progress possible, and gave eventually to its conclusions the widest publicity that circumstances permitted; may I say that it smoothed the way for achievements in which it could take no active part, and in some few instances perhaps rendered them almost inevitable. Let me support these views by a few typical examples.

#### PROGRESS IN WHEAT GROWING.

I shall deal with Wheat in the first place, and in greatest detail, because, as you know, it lies at the basis of all our farming interests, and is indeed the sheet-anchor of our national prosperity. I have already shown that by the end of the 40 years under consideration our area under Wheat had more than doubled, and our production increased by more than three and a half times; this improvement in production, both actual and relative, is undoubtedly due to general improvement in farming methods. How has this been brought about? First, by an intelligent study of the problems of wheat growing under conditions at the time comparatively unknown; and, secondly, by dissemination of the knowledge acquired throughout the length and breadth of the land.

#### PREPARATION OF THE LAND.

We all know to-day that the first essential to a successful Wheat Crop in this State is adequate preparation of the land; without it, apart from very exceptional seasons, we can anticipate nothing better than mediocre crop yields. We have learnt, too, that with the large individual areas usually sown, coupled with the usually late arrival of Autumn rains, that it is practically impossible to get land ready for Wheat in the course of the season in which it is sown; from these facts has arisen the practice of fallowing land in the Winter months immediately preceding sowing. If we examine Table I. we shall see that in the first decade the mean area treated as Bare Fallow was a little over half a million acres, or 2.9 acres under wheat for every acre fallowed; in the fourth decade the mean area fallowed was over one and three-quarter million acres, or 1.4 acres under wheat for every acre fallowed. The increase in area of Wheat sown on Bare Fallow has therefore been both actual and relative; but the improvement in practice does not end there. We know very well to-day that there is both "fallow" and "fallow"; and those amongst us who are old enough can recall very well the difference between "fallow" of 40 years ago and "fallow" of to-day; and the Department can claim some credit for this improvement that has been very largely responsible for the steady increase in our mean Wheat yields. The work in this connection was first started at Roseworthy Agricultural College and extended subsequently

to the various Experimental Farms; and as in the course of years results secured became apparent, they were given publicity through the pages of the *Journal of Agriculture*, through the daily press, and in the course of public Lectures. Many will recall Professor Lowrie's telling addresses on the subject, and his work has been continued since by other officers. I must add here that our propaganda on this and other subjects would never have proved as effective as it has proved had it not been for the existence of the Agricultural Bureau system in our midst. It is this system that has enabled us to reach farmers most effectively; by its means Departmental Officers have secured the confidence of some of the best men of the farming districts; the latter have adopted our recommendations, and their example has subsequently acted as leaven which has spread through the farming community and led to immense improvement in our wheat yields.

#### USE OF SUPERPHOSPHATE.

Next in importance to soil tillage comes the regular dressing of soluble phosphates to sown crops. Here, again, credit for initiation of the practice must be given to the first Principal of the Roseworthy Agricultural College, Professor J. D. Custance, and for intensive propaganda on the subject by his successor, Professor W. Lowrie; since their time the whole question of the application of these phosphates to both crops and pastures has been closely studied by departmental officers. Our combined work, extending over the whole of our agricultural areas, goes to show that at current prices for Wheat and Fertilisers maximum economic results are usually secured with dressings of 180lbs. of 45 per cent. Superphosphate; we have also shown that the less soluble basic phosphates and the more or less insoluble ground rock phosphate are both unsatisfactory as crop dressings over the bulk of our territory. That our work in this direction has been confirmed in every-day practice, and that our propaganda on the subject has proved effective, is shown by the fact that whilst in 1897-98 it is estimated that we had 60,000 acres, or 2.9 per cent. of the area cropped, dressed with 2,000 tons of Superphosphate, corresponding figures for 1928-29 were 4,251,348 acres, or 91.2 per cent. of the area cropped, and 172,000 tons, increases in 32 years of 6,986 and 8,500 per cent. respectively.

Farmers are often accused of being conservative in their practices; nor is such an attitude altogether unreasonable when questions involving a livelihood are at stake. The vagaries of the weather are usually sufficiently perplexing to satisfy the farmer's gambling instinct. In the circumstances the rapidity of the spread of superphosphate over our rural areas is all the more remarkable, particularly when we recollect that it involved more than the systematic use of a fertiliser. It included as well a complete revolution in methods of seeding, the supersession of the old broadcaster and the sowing of 50 to 80 acres a day, by the old drills which in earlier days rarely did more than 12 to 15 acres. Professor Custance was advised to place his drill in the Adelaide Museum.

#### TOP DRESSING.

In the course of time, it was noted that the growth of natural feed on the stubbles of fertilised Wheat crops was infinitely superior in quantity and feeding value to the normal type of feed that grew on unfertilised fields, and that in such circumstances the residual phosphate increased the carrying capacity of land temporarily out of cultivation very considerably. More recently, following on these observations, the practice of top dressing pastures, particularly in our moister districts, has come into vogue. This practice has received special attention on the Kybybolite Experimental Farm. We have been able to show on this Farm that, whilst the carrying capacity of unmanured natural pasture gradually deteriorates, that of adequately dressed land, neither broken with the plough nor sown to grasses, rose from three-fourths of a sheep to the acre to over three sheep in the course of nine years.

The areas of pasture lands top dressed with phosphates were not recorded until 1924-25, and available Statistical data are as follows:—

|                   | Areas Dressed. | Superphosphate |
|-------------------|----------------|----------------|
|                   | Acres.         | Used.<br>Tons. |
| 1924-25 . . . . . | 67,124         | 4,080          |
| 1925-26 . . . . . | 123,657        | 7,380          |
| 1926-27 . . . . . | 162,355        | 9,110          |
| 1927-28 . . . . . | 209,122        | 11,393         |
| 1928-29 . . . . . | 250,413        | 13,029         |

#### OTHER MANURES.

I am of the opinion, too, that in negative fashion the Department of Agriculture has been of assistance to Wheat Growers in testing the local value of the other two main lines of fertilisers, namely, nitrogenous and potassic manures. We have shown very definitely that apart from very exceptional cases the use of these fertilisers by local cereal growers can only result in serious losses. We have also endeavored to protect them, although not always successfully, against insidious propaganda of "quack" preparations.

#### IMPROVED SEED.

Another contributing factor to locally improved Crop yields has been the systematic use of high-class seed adapted to local conditions. In this connection, there are three points that are involved:—

1. The adaptability to climate and soil of the varieties in use;
2. Their yielding capacities; and
3. The general condition of the seed used.

And, whilst I claim that the Department has done good work covering all these points, I recognise that it has not been alone in the field. It is only necessary to mention such well-known names as those of Richard Marshall, Frederick Coleman, Oliver Badman, W. J. Marshman, &c., to make that point clear. Nevertheless, work of considerable value in this direction has been carried out both at the Roseworthy Agricultural College and on the Experimental Farms. Since 1905 this question has received attention at the Agricultural College from two points of view, namely, the creation of new and improved varieties adapted to local conditions, and the maintenance of high yielding characteristics by systematic selection in both new and old varieties. That this work has proved eminently successful is shown by the extent to which older varieties have been displaced by new Roseworthy Wheats. In 1928-29 out of a total area sown to Wheat of 3,775,601 acres, 1,342,031 acres, or 35.55 per cent. were sown to College bred wheats, and if we take into consideration that that well-known old Wheat, *Guyas*, was taken in hand by the College in 1905 and separated into three separate varieties, and improved by constant selection, it can probably be said that half the Wheat sown in South Australia is connected directly or indirectly with the breeding or selection Plots of Roseworthy Agricultural College. In this direction alone the influence of the College on the productivity of our Wheat Fields has been very beneficial.

As to the third point, namely, the character of the seed sample sown, we have also assisted by means of propaganda. There was an old prejudice prevalent in earlier days, namely, that any kind of sample would do for seed. I have heard it maintained, for example, that the smallest grains were most suitable for seed, because there were more of them to the bushel. By consistently advocating that only the best, cleanest, well ripened and well cared for sample should be used we have helped farmers to better crops.

#### DISEASES.

Finally, there is the question of disease. I have not the time to go into details here, but I shall say that we have consistently studied the problems as they arose and made known what precautionary or repressive measures appeared to meet the case, and to this extent we have assisted farmers to more profitable crops.

USE VOCO POWER FOR THE 1930 HARVEST

# More Work *per* Gallon!

For every harvest job there is real economy — more work at no extra cost — in Voco POWER Kerosene.

VOCO is correctly volatile and packed with knock-proof power — and the more power the more work per gallon.

Use VOCO this harvest and cut down your power costs.

THERES WORK IN EVERY DROP

## MONEY VALUE TO IMPROVED METHODS.

What has this meant to the farming community and the State as a whole in terms of hard Cash? If we take the 30-year period extending between 1876 and 1906 we shall see that the mean yearly area under Wheat was 1,668,449 acres and the mean total production 9,834,367bush., representing a mean yield per acre of 5.89bush. If, on the other hand, we take the 20-year period extending from 1906 to 1926, we find the mean area under Wheat to have been 2,227,472 acres and mean total production 24,797,753bush., or 11.13bush. per acre. Hence, during the 20-year period ending in 1926, the mean production of Wheat per acre was approximately twice that of the immediately preceding 30 years, an achievement of which both the farmers concerned and the Department of Agriculture have good reason to be proud.

It will be observed that in this period of 30 years (1876-1906) are included the first 20 years of the existence of the Department of Agriculture (1886-1906), and the fact that over that period little progress could be registered for Wheat growing is an indication of the difficulties that had to be overcome in the initial stages of our work. We had in the first instance to determine along what lines progress could best be achieved, and in the second we had to gain the confidence of the farming community and convince it of the soundness of the methods we advocated. The value to the State of the general adoption of improved farming practices in the second 20 years of the Department's existence, when our influence had begun to be felt, can be expressed in terms of hard cash as follows:—

Between 1906 and 1926 (20 years) we produced 495,955,000bush. of Wheat as against 295,031,000 in the immediately preceding 30 years. Had production in the 1906-1926 period been on the same low scale as in 1876-1906 period, i.e., 5.89bush. to the acre, we should have had 262,396,000bush. only. The difference between what we actually secured and what we might have secured (233,559,000bush.) represents the fruits of the extension of better farming methods, towards which we believe the Department of Agriculture contributed no small part. Over this 20-year period Wheat averaged at Port Adelaide in the neighborhood of 5s. a bushel. The gain to the State from improved farming has therefore been represented approximately during this period of 20 years by £58,390,000, or close on £3,000,000 per annum from Wheat alone.

The contribution of the Department of Agriculture towards this State gain of £3,000,000 per annum from Wheat alone is perhaps more or less intangible, and therefore difficult to express in terms of hard cash. It is nevertheless fair to state that, whilst many of our foremost farmers could probably have got along without departmental guidance, this cannot be said of the average man, whom we have certainly helped to higher mean yields of Wheat. At what rate can we assess this service that we have rendered to the average man and therefore to the State as a whole? If, in our modesty, we claim 1bush. an acre on the mean area under Wheat during these 20 years, shall we be going too far? If not, our services over a period of 20 years will have been worth over £500,000 per annum to the farming community and the State from Wheat returns alone.

## OTHER DEPARTMENTAL ACTIVITIES.

I have dwelt in some detail upon the relationship of Wheat to the Department, because it covered matters in which you were chiefly interested, and because, after all, it represents our main agricultural and State concern. I need not add, however, that the activities of the Department have not been confined to Wheat, but for fear of wearying you, I can do no more than touch upon other matters in which the Department has been concerned.

We have done much to emphasise the advantage of associating Live Stock, particularly Sheep, with the growing of Cereal Crops. This question was given special attention when I was in charge of the Roseworthy Agricultural College. As a result of 10 years'

experience on the subject I was able to show that the College Farm had averaged a sheep to the acre on the whole area, notwithstanding the fact that two-fifths of the area was under Cereals, two-fifths treated as Bare Fallow and under forage crops, and one-fifth only available wholly for pasture purposes. Since my time, my successor, Mr. Colebatch, made a close study of the types of Sheep best adapted to the production of Export Fat Lambs. The handling of Live Stock on Farms naturally led to the question of grazing crops and hand-feeding generally, which is unavoidable for portion of the year on any farm on which Live Stock is kept. I am afraid that the advocacy of general association of Live Stock with crops must be described as one of those things in which the Department has not yet been completely successful. I am of the opinion that in the course of time both our Dairy Cows and our Sheep can be doubled in this State without appreciable reduction in areas at present sown to Wheat.

Whilst on this subject, I would like to state that excellent pasture improvement work has been carried out by us on the Kybybolite Experimental Farm. It is true that this work is applicable essentially to the South-East and our districts of heavy rainfall. It affects, nevertheless, districts the past productivity of which has been low and which may be counted upon in the future to swell our rural production very considerably.

Through our Berri Experimental Orchard we have endeavored to accumulate data of immediate value to River Orchardists, and the same can be said of the Blackwood Orchard for the Hills district.

At Parafield, Egg Laying strains of Fowls have been raised to a high degree of perfection, and their progeny has been distributed all over the State at reasonable rates, and has contributed very appreciably towards general improvement in our Poultry Industry. In this connection I would like to express appreciation of the sterling work done by Mr. D. F. Laurie, who after long association with the Department, has recently retired into private life.

It has often been said that South Australia was not a Dairying State, chiefly because of the inadequacy of our natural pastures from the viewpoint of cows in milk. The flush period is of short duration and cows soon find themselves on dry feed, which, however suitable for sheep, is not favorable to heavy milk production. Nevertheless, as a Department we have faith in the Dairy Industry even under these conditions. I need not remind you that in the dry Nineties cows and fowls enabled many a struggling wheatfarmer to keep on the land. With the fall in prices of Wheat and Wool, history would appear to be repeating itself, and once again farmers are coming to recognise that the vagaries of seasons and markets render unwise specialisation in any one form of rural activity to the exclusion of all others. Our view is that, wherever practicable, the revenues of every farmer should include eggs, cream, and to some extent pigs. Butter, Cheese, Eggs, and Bacon are commodities for which there is world-wide demand, and we look to farmers to help us to double South Australia's present output. Departmentally we have to admit that, notwithstanding active propaganda on the subject, progress in dairying has not been one of our successes, and much as we deplore them we look to the bad times through which we are passing to assist us in overcoming the average South Australian's aversion to cows. Apart from propaganda and instructional work, we have endeavored to assist Dairymen by forming Herd Testing Associations, the main object of which is the elimination of the unprofitable cow, coupled with the proof—if any were needed—that it does not pay to starve cows. We have also undertaken the testing of the milk supply of pure bred herds and established a subsidy scheme, by means of which Dairymen can secure Bulls from heavy milking ancestry at reasonable rates. Both schemes should, in the course of time, tend to improve very considerably the productivity of our herds.

We have also given special attention to Farm Economics at the Turretfield Demonstration Farm, which over the past nine years has been worked upon strictly business lines. Among other things, we have shown what have been the mean inclusive costs of main Farm Crops in a district of this kind, the mean costs of upkeep of a Fat Lamb Flock, and the usual costs of various farm manual operations.

On our four Experimental Farms we have endeavored to solve the farming problems of the districts in which they are situated, and we have used them for the supply to farmers of improved pedigree Seed Wheat, Oats, and Barley.

In other directions the Department of Agriculture is concerned in activities which, although at times less pleasant, have nevertheless an indirect bearing upon the successes and failures of the rural community. I refer to our inspectional and police duties that form part of the administration of various Acts. Among other things, it is our duty to watch over the manufacture and distribution of fertilisers, to keep an eye on Chaff Mills and the sale of Insecticides and Fungicides, to enforce the provision of Acts dealing with the control of Plant Diseases. In the latter connection, it is one of our triumphs that we should have been able to keep South Australia free from the Phylloxera, which has destroyed the Vineyards of neighboring States. The recently enacted Dairy Act will compel us to watch both the sellers of Cream and the manufacturers of Butter. All these Acts have been passed in the interests of rural production, and however disagreeable their enforcement may at times prove, we believe it to be our duty, both in the interests of rural producers and of the State, to give effect to them with rigid impartiality.

Finally, I come to our educational efforts. Roseworthy Agricultural College, as you know, takes young men in hand and strives to impart to them sound technical training in agricultural subjects adapted to local conditions. I need not stress this point. Roseworthy graduates occupy important positions in the various Departments of Agriculture; they are known as successful farmers, graziers, fruitgrowers, vinegrowers, dairymen, &c., in various parts of the State; they are even to be found in Parliament, on the Supreme Court benches, and in the pulpit. Nor have we lost sight of the value of adult education. We have agricultural, dairy, and fruit instructors in various parts of the State whose business it is to visit producers on their holdings and give such advice as may be required. We have organised Demonstration Plots on private farms and in association with Branches of the Agricultural Bureau all over the State. We have established Crop Competitions, Pruning Matches, &c., with a view to stimulating production and improving the practice of manual operations. We are frequently called upon to tender advice by correspondence. I find that apart altogether from the Roseworthy College and such correspondence as may be undertaken by District Instructors, we sent from the Adelaide Office alone during the 12 months ending on June 30th close on 1,800 letters of advice to rural producers. We have soils and waters analysed free of charge to producers whenever the circumstances appear to warrant it; in 1928-29 about 230 such analyses were carried out. We publish, too, a *Journal of Agriculture* and issue Bulletins on matters of special or general interest to farmers. And, finally, we have the Agricultural Bureau system, than which I know of no institution better calculated to give the rural community a common rallying ground, from which mutual help can be given and grievances ventilated.

I have touched on many points in this address, in many cases very lightly, and I fear altogether inadequately. I hope, however, that in some measure I have justified the existence of the Department of Agriculture. Personally I have been associated with it in various capacities for close on 40 years, and I am prepared to assert that, apart from very minor exceptions, officers of the Department have always been alive to their duties and endeavored to give effect to them to the best of their abilities and to the extent that available funds permitted.

# FIELD PEASE AND OATS V. MEGGITT'S NUTS.

[By PROFESSOR A. J. PERKINS, Director of Agriculture.]

[*Reply to a question, "How do Field Pease at 5s. 9d. per bushel and Oats at 2s. 6d. per bushel compare for Price and Food Values with Meggitt's Nuts, £14 per ton at Port Adelaide?" submitted by the Port Elliot Branch at the Conference of Southern Branches, Murray Bridge, August 20th, 1930.*]

The comparison of different Foodstuffs one with the other is not always easy, particularly when they differ widely in character, as for instance "Hay Chaff" on the one hand and a concentrated Foodstuff on the other, such as Meggitt's Nuts. The comparison between Pease and Oats, and Meggitt's Nuts is, however, much simpler. The results are determined on the food units present in each foodstuff; and towards that end each foodstuff is compared to one special substance taken as unit. In earlier times an attempt was made to use "meadow hay" as a standard, but results were generally unsatisfactory. More recently "Starch" has been adopted as the standard of comparison, and what is known as the Starch Equivalent of a foodstuff is the number of pounds of Starch required to give rise to the same feeding results as 100lbs. of the foodstuff under consideration. Starch Equivalence is based on the analysis of the Foodstuff coupled with direct tests of the digestibility of the foodstuff under consideration.

In Table I. I have given the usual Organic Analysis of the three foodstuffs under consideration, together with Wheat and Bran:—

TABLE I.—*Showing Organic Analysis of Foodstuffs.*

|                   | PEASE. | OATS. | MEGGITT'S<br>NUTS. | BRAN. | WHEAT. |
|-------------------|--------|-------|--------------------|-------|--------|
|                   | %      | %     | %                  | %     | %      |
| Moisture .....    | 14.0   | 13.3  | 10.6               | 12.2  | 13.4   |
| Ash .....         | 2.8    | 3.1   | 6.1                | 3.6   | 1.7    |
| Protein .....     | 22.5   | 10.3  | 27.0               | 16.4  | 12.1   |
| Fats .....        | 1.6    | 4.8   | 6.9                | 2.6   | 1.9    |
| Fibre .....       | 5.4    | 10.3  | 9.8                | 8.4   | 1.9    |
| Starches, &c..... | 53.7   | 58.2  | 39.6               | 56.8  | 69.0   |
|                   | 100.0  | 100.0 | 100.0              | 100.0 | 100.0  |

In comparison with the four other foodstuffs Meggitt's Sheep Nuts has less moisture, and therefore a higher proportion of available Dry Matter. This is, however, neutralised by the higher Ash Content, which leaves available organic matter very similar in all five foodstuffs, the highest being Wheat with 84.9 per cent., and the lowest Pease with 83.2 per cent. The chief characteristic of Meggitt's Nuts is a high proportion of crude protein—27 per cent. and of Fats, 6.9 per cent.

Pease, on the other hand, are rich in crude Protein, 22.5 per cent., but poor in fats, 1.6 per cent., whilst Oats are richer in Fats, 4.8 per cent., but poorer in Protein, 10.3 per cent.

In this connection it should be noted that whilst Protein is the characteristic substance entering into the composition of flesh and muscle—lean meat is almost pure protein—and forms important parts of milk, wool, &c. Starches, Fats, and Fibre are responsible mainly for the formation of body fat and the development of energy.

The value of a Foodstuff cannot, however, be based exclusively upon its chemical composition; much depends upon the digestibility of the various food units; the extent to which the latter are digestible has been indicated below in Table II.

TABLE II.—*Indicating Percentage Digestibility of the Five Foodstuffs.*

|                              | PEASE. | OATS. | MEGGITT'S<br>NUTS. | BRAN. | WHEAT. |
|------------------------------|--------|-------|--------------------|-------|--------|
|                              | %      | %     | %                  | %     | %      |
| Digestible Protein .....     | 19.4   | 8.0   | 23.3               | 13.0  | 10.2   |
| Digestible Fats .....        | 1.0    | 4.0   | 6.3                | 1.8   | 1.2    |
| Digestible Fibre .....       | 2.5    | 2.6   | 3.1                | 2.2   | 0.9    |
| Digestible Starches, &c. ... | 49.9   | 44.8  | 30.9               | 40.3  | 63.5   |
| Foodstuff Value .....        | 98     | 95    | 97                 | 77    | 97     |
| Starch Equivalent .....      | 68.6   | 59.7  | 69.0               | 46.2  | 73.2   |

It must be understood that in every instance the figures given in Table II. have reference to first-class samples only, and that any inferiority in the sample would lead to corresponding depression of the figures given. The last figures in the Table—Starch Equivalents—set out the relative value of each foodstuff on parity of weight; that is to say, in the matter of Food Values 100lbs. of Pease would be equivalent to 68.6lbs. of Starch, 100lbs. of Oats to 59.7lbs., &c. The value of the Foodstuffs are therefore inversely proportional to their Starch Equivalents; and it is in this fashion that their relative money values can be determined. These have been indicated in Table III. in terms of each foodstuff successively.

TABLE III.—*Showing Relative Monetary Value of Foodstuffs.*

|                          | £ s. d. | £ s. d. | £ s. d. | £ s. d. | £ s. d. |
|--------------------------|---------|---------|---------|---------|---------|
| Meggitt's Nuts 2,000lbs. | 14 0 0  | 9 18 5  | 9 12 9  | 7 5 4   | 5 10 0  |
| Bran ..... 2,000 "       | 9 3 5   | 6 10 0  | 6 6 3   | 4 14 8  | 3 12 0  |
| Pease ..... 60 "         | 0 8 4   | 0 5 11  | 0 5 9   | 0 4 4   | 0 3 3   |
| Oats ..... 40 "          | 0 4 10  | 0 3 5   | 0 3 4   | 0 2 6   | 0 1 11  |
| Wheat ..... 60 "         | 0 9 0   | 0 6 4   | 0 6 2   | 0 4 7   | 0 3 6   |

It will be seen that the four foodstuffs in order of present-day market values are more costly in the following order:—

1. Meggitt's Nuts
2. Bran
3. Pease
4. Oats
5. Wheat

The requirements of a 100lbs. Sheep, both for maintenance and Fattening ration, may be summarised as follows:—

*For daily Maintenance Ration—*

|                             |               |
|-----------------------------|---------------|
| Starch Equivalent .. . . .  | 0.83lbs.      |
| Dry Matter .. . . .         | 1.8 — 2.3lbs. |
| Digestible Protein .. . . . | 0.12lbs.      |

*For Fattening purposes—*

|                             |               |
|-----------------------------|---------------|
| Starch Equivalent .. . . .  | 1.45lbs.      |
| Dry Matter .. . . .         | 2.4 — 3.2lbs. |
| Digestible Protein .. . . . | 0.19lbs.      |

Below are given typical rations, based on the above:—

| Maintenance Rations. |         |          | Fattening Rations |          |       |
|----------------------|---------|----------|-------------------|----------|-------|
|                      |         | Cost.    |                   |          | Cost. |
| 1. Chaff .....       | 1½ lbs. | } 1·89d. | 1½ lbs.           | } 2·43d. |       |
| Pease .....          | ½ "     |          | ½ "               |          |       |
| Barley .....         | —       |          | 1 "               |          |       |
| 2. Chaff .....       | 1½ lbs. | } 1·69d. | 1½ lbs.           | } 2·44d. |       |
| Oats .....           | ½ "     |          | 1½ "              |          |       |
| 3. Chaff .....       | 2 lbs.  | } 1·89d. | 1½ lbs.           | } 2·44d. |       |
| Bran .....           | ½ "     |          | ½ "               |          |       |
| Barley .....         | —       |          | 1 "               |          |       |
| 4. Chaff .....       | 1½ lbs. | } 1·90d. | 1½ lbs.           | } 2·44d. |       |
| Meggitt's Nuts ..... | ½ "     |          | ½ "               |          |       |
| Barley .....         | —       |          | 1 "               |          |       |
| 5. Chaff .....       | 1½ lbs. | } 1·48d. | 2 lbs.            | } 2·29d. |       |
| Wheat .....          | ½ "     |          | 1½ "              |          |       |

Prices adopted:—

|                  | £ | s. | d. |                   | £ | s. | d. |
|------------------|---|----|----|-------------------|---|----|----|
| Chaff .. . . . . | 7 | 0  | 0  | Barley .. . . . . | 0 | 2  | 3  |
| Pease .. . . . . | 0 | 5  | 9  | Bran .. . . . .   | 6 | 10 | 0  |
| Oats .. . . . .  | 0 | 2  | 6  | Wheat .. . . . .  | 0 | 3  | 6  |

From the above will be noted that at current prices Wheat is to-day the cheapest livestock Foodstuff on the market.

## APPLES FOR LIVESTOCK.

[By W. J. SPAFFORD, Deputy Director of Agriculture.]

In South Australia there are over 10,000 acres carrying Apple trees, and in some seasons the quantity of fruit which falls to the ground or is excluded from our markets because of other defects is really enormous. Many apple-growers regularly utilise all fallen apples as feed for livestock; still others allow the waste fruit to decompose where it falls, and as this latter practice not only leads to the encouragement of the diseases and pests to which the apple tree is liable, but means the destruction of an animal foodstuff of proved value, it should be avoided wherever possible. To show just what the waste of foodstuff is, we had apples grown at Dingabledinga in 1929-30 analysed in April to show their nutritive value, with the following results:—

### *Analysis of Apples, 1929-30.*

|                     | Sample as<br>Received. | Oven Dry<br>Sample. |
|---------------------|------------------------|---------------------|
|                     | %                      | %                   |
| Moisture .....      | 79.00                  | —                   |
| Ash .....           | 0.50                   | 2.38                |
| Protein.....        | 0.31                   | 1.48                |
| Fat .....           | 0.69                   | 3.28                |
| Carbohydrates ..... | 18.21                  | 86.72               |
| Fibre .....         | 1.29                   | 6.14                |
|                     | <u>100.00</u>          | <u>100.00</u>       |

### VALUE OF APPLES AS A FOODSTUFF.

As with all other bulky “green” foodstuffs, Apples when fresh contain a lot of water, but this is not a disadvantage for farm livestock, with the possible exception of horses when on heavy work; still it means that these watery articles should always be fed to animals in conjunction with drier and more concentrated foodstuffs. In estimating the feeding value of Apples, it can only be done by comparing them with other foodstuffs of the same type, all of which are fed to animals in admixture with drier foodstuffs, and for the purpose this has been done, and we have taken Turnips, Potatoes, and Sugar Beet, and besides showing the chemical analysis of each, we have also presented the amounts of digestible nutrients and also the *Starch Equivalent* value of all of them.

### *Comparison of Apples with Other Well-known Foodstuffs.*

|                          | APPLES.<br>Nutrients. |         | TURNIPS.<br>Nutrients. |         | POTATOES.<br>Nutrients. |         | SUGAR BEET.<br>Nutrients. |         |
|--------------------------|-----------------------|---------|------------------------|---------|-------------------------|---------|---------------------------|---------|
|                          | Crude.                | Digest. | Crude.                 | Digest. | Crude.                  | Digest. | Crude.                    | Digest. |
|                          | %                     | %       | %                      | %       | %                       | %       | %                         | %       |
| Moisture .....           | 75.00                 | —       | 75.00                  | —       | 75.00                   | —       | 75.00                     | —       |
| Ash .....                | 0.60                  | —       | 2.06                   | —       | 1.10                    | —       | 0.70                      | —       |
| Protein.....             | 0.37                  | 0.23    | 2.65                   | 1.76    | 2.10                    | 1.10    | 1.30                      | 0.90    |
| Fat .....                | 0.82                  | 0.41    | 0.29                   | 0.14    | 0.10                    | 0.05    | 0.10                      | 0.05    |
| Carbohydrates ..         | 21.67                 | 19.98   | 17.64                  | 16.17   | 21.00                   | 18.90   | 21.40                     | 20.30   |
| Fibre .....              | 1.54                  | 0.47    | 2.35                   | 0.88    | 0.70                    | —       | 1.50                      | 0.50    |
| <b>Starch Equivalent</b> | <b>19.3</b>           |         | <b>14.6</b>            |         | <b>20.0</b>             |         | <b>16.3</b>               |         |

*Note.*—The analyses for Potatoes and Sugar Beet are actual, whereas the figures for Turnips and Apples have been calculated after reducing the moisture content to 75 per cent., to bring all four foodstuffs to the one level.

The *Starch Equivalent* values set out above can be used to compare these foodstuffs when they are to be used for fattening or maintenance purposes, and they show that (a) Apples are almost as good a foodstuff, weight for weight, as are Potatoes with the same moisture content, (b) they are better than Sugar Beet, and (c) are of considerably higher feeding value than Turnips, even after this latter foodstuff has been wilted down to the point where it only contains 75 per cent. of moisture.

#### FEEDING APPLES TO FARM LIVESTOCK.

Fed in conjunction with other more concentrated foodstuffs, Apples should prove very valuable for dairy cows, and should be useful for maintaining and even fattening cattle, sheep, and pigs. In this connection it is suggested that the following daily rations would utilise Apples to full advantage:—

*In-Milk Cows, weighing about 1,000lbs.*

|                    | Daily Milk Yield. |        |        |        |
|--------------------|-------------------|--------|--------|--------|
|                    | 10lbs.            | 20lbs. | 30lbs. | 40lbs. |
|                    | Lbs.              | Lbs.   | Lbs.   | Lbs.   |
| Apples .....       | 12                | 14     | 14     | 14     |
| Hay Chaff .....    | 15                | 15     | 15     | 15     |
| Bran .....         | 5                 | 11     | 15     | 15     |
| Linseed Meal ..... | —                 | —      | 1      | 4      |

*Dry Cows to Calve* (per 1,000lbs. live weight):—

Apples 25lbs., Straw 18lbs., Bran 2lbs.

*Fattening Cattle* (per 1,000lbs. live weight):—

Apples 40lbs., Hay 12lbs., Bran 5lbs.

*Maintenance Ration for Cattle* (per 1,000lbs. live weight):—

Apples 40lbs., Barley or Oat straw 12lbs.

*Fattening Sheep* (per 100lbs. live weight):—

(1) Apples 4lbs., Hay 1lb., Bran  $\frac{1}{2}$ lb. or

(2) Apples 5lbs., Oats  $\frac{1}{2}$ lb., Bran  $\frac{1}{2}$ lb.

*Maintenance Ration for Sheep* (per 100lbs. live weight):—

Apples 4lbs., Barley or Oat straw 1lb.

*Pigs (Breeding sows):—*

Apples 10lbs., Skim-milk 5lbs., Peas 1lb.

## ROSEWORTHY AGRICULTURAL COLLEGE.

SEVENTH REPORT ON THE PERMANENT FIELD EXPERIMENTS,  
SEASONS 1904-1928.

[By W. R. BIRKS, B.Sc. (Agric.), Principal, and T. A. Cole, D.D.A., Experimentalist.]

(Continued from page 36, August, 1930.)

14. *Crop Rotation Experiments*—continued.

(e) *Fallow-Wheat-Pease-Wheat-Barley*.—This is an extension of the rotation dealt with in the previous paragraph. Barley is again associated with wheat as a stubble crop, and the attempt is made to determine whether one period of fallow can be made to suffice for two wheat crops with a grazed-off pea crop placed between them. This gives three grain crops in five years, together with a fodder crop which should help to counteract the ill effects to the soil to be expected from the intensive system of cropping employed. The cereal crops in this rotation received 2cwts. superphosphate per acre at each seeding and the pea crop 1cwt. The series was commenced in 1911, when the entire area to be used was in fallow. As the second wheat and the barley crops required to be sown on unfallowed land, these crops were not sown in the first year, and there are the results of 11 years to be dealt with in the case of these two as against 12 years of the first wheat crop. The series was closed along with others in 1922. The grazing figures were not recorded, except in the case of the pea crop, until well on in 1916, so that there are the results of only six years' work from which to take mean grazing returns. In the next table are shown the details of crop returns from this rotation for 1916 onwards, together with mean results for 11 or 12 years as the case may be.

TABLE XLVII.—*Showing Crop Returns from Fallow-Wheat-Pease-Wheat-Barley Rotation, 1911-1922.*

| Year.                       | Total Produce. |    |    |            |    |     | Grain Yields. |           |            |           |           |         |

Before proceeding to the consideration of these results, those from the pea crop, recorded as sheep grazing, are to be noted in the next table along with all other grazing afforded by the rotation. For the fallow grazing the figure previously employed (.25) is again assumed to apply. In each other case the figure represents the equivalent number of sheep which the records show the pasture would have supported for a period of a year.

TABLE XLVIII.—*Showing Grazing Value, as Sheep per Acre for a Year, of Land Available for Stocking in Fallow-Wheat-Pease-Wheat-Barley Rotation, 1917-1922.*

| Year.                                           | Before<br>Fallowing. | Fallow.  | 1st Wheat<br>Stubble. | Pea<br>Crop. | 2nd Wheat<br>Stubble. | Barley<br>Stubble. | Total. |

| Values at 12s.<br>6d. per sheep<br>per annum... | 2s. 9d.              | 3s. 1½d. | 8s. 3d.               | 20s. 10½d.   | 5s. 10½d.             | 7s. 9d.            | £2 8 9 |

The results indicated in the tables above are not satisfactory from an economic point of view. In the first place the pea crop has yielded grazing for less than the equivalent of two sheep per acre for a year. From the mean grazing figures recorded in Tables XLI. and XLV. it is apparent that stubble land left out of cultivation for a year might be expected to carry as much stock as this without the expense of putting in a crop. Further, although the mean returns from the first wheat crop are only slightly below normal, the second wheat and barley crop returns are so poor that the costs of cultivation plus rent are not covered in either case. It is not surprising, therefore, to find that the rotation as a whole shows a definite net loss as far as grain returns at least are concerned; working on the hay figures, a small profit can be shown. In the next table will be seen the calculations based on the mean figures recorded in the previous two tables. Although various periods are involved, the discrepancies thus introduced in calculating net returns are probably negligible. Costs of production estimates are based on a scale of figures similar to that previously employed. Thus, 50s. per acre is allowed for wheat growing on fallow, plus 4s. 6d. for the extra hundredweight of superphosphate used in this case, and 35s. for the barley crop with a similar addition of 4s. 6d. The second wheat crop is assumed to cost as much as the barley, and for pease, which are not harvested, the figure of 30s. per acre is adopted.

 TABLE XLIX.—*Showing Gross and Net Monetary Returns from Fallow-Wheat-Pease-Wheat-Barley Rotation, 1911-1922.*

| Receipts—                                                                 | Grain. |    |         | Hay. |    |           |

| Costs of cultivation—                                                     |        |    |         |      |    |           |
| First wheat crop (2cwt Super) .....                                       | 2      | 14 | 6       | 2    | 14 | 6         |
| Pea crop (1cwt. Super) .....                                              | 1      | 10 | 0       | 1    | 10 | 0         |
| Second wheat crop (2cwt. Super) .....                                     | 1      | 19 | 6       | 1    | 19 | 6         |
| Barley crop (2cwt. Super) .....                                           | 1      | 19 | 6       | 1    | 19 | 6         |
| Total expenditure per acre for 5 years .....                              | 10     | 13 | 6       | 10   | 13 | 6         |
| Difference between Receipts and expenditure per<br>acre for 5 years ..... | 0      | 3  | 9 loss. | 0    | 4  | 2 profit  |
| Net result per acre per annum .....                                       | 0      | 0  | 9 loss  | 0    | 4  | 10 profit |

It appears then that whatever may be the case in other districts of better rainfall, the attempt to extend the rotation to include more than two crops following a period of fallow has not met with success in this case. Barley gave a definitely remunerative

return in rotation with fallow and wheat (paragraph (d) ), but in that case it possibly drew some residual benefit from the fallow. In the longer rotation this residuum, if it exists, is apparently thoroughly exhausted, and even the second wheat crop following pease shows a small loss, on grain returns at least, on the most liberal possible interpretation of the question of costs and prices.

(f) *Fallow-Wheat-Lucerne-Lucerne-Lucerne*.—In this series of plots lucerne seed at the rate of 10lbs. per acre was broadcast and harrowed in immediately after drilling in the wheat plot each year. The lucerne thus came away in the wheat stubble and supplemented the natural growths of herbage in the subsequent three years. The effect it had in increasing the carrying capacity of these plots may be gauged from the figure representing the mean grazing return in the three "pasture" years. This is 2.07 as against 1.75, representing the carrying capacity of pasture consisting of natural growths only in the third year of the fallow-wheat-pasture rotation reported upon in paragraph (d) ) above. With the limited summer rainfall occurring locally then, lucerne has given a relatively small increase only in grazing returns; an increase which even in three years has been insufficient to cover the cost of the seed used. The rotation as a whole, however, has given quite satisfactory results, as will be shown in the tables following. It is adapted, of course, to conditions in which stock grazing is of more importance than cropping, and the major part of the gross returns is consequently shown in the grazing values.

A feature of the crop returns in this series is the relatively high hay yields as compared with grain returns. Thus, although the mean grain yield is practically identical with that recorded in the previous series (paragraph (e) ), the hay returns are approximately 8cwts. or 24 per cent. better. This relatively high hay yield is a result no doubt of the supplies of nitrogen and organic matter returned to the soil as a result of the growth of lucerne and the long period of grazing.

The full details of the crop returns are shown in next table.

TABLE L.—*Showing Crop Returns from Fallow-Wheat-Lucerne-Lucerne-Lucerne Rotation, 1914-1922.*

| Year.                  | Grain.     | Total Produce. |    |     |
|------------------------|------------|----------------|----|-----|
|                        | Bush. lbs. | T.             | C. | L.  |
| 1914 .....             | 5 26       | 0              | 9  | 90  |
| 1915 .....             | 17 10      | 2              | 11 | 73  |

| Means for 9 Years..... | 16 15      | 1              | 14 | 81  |
| Hay equivalent .....   | —          | 2              | 2  | 39  |
|                        | £ s. d.    | £              | s. | d.  |
| Values .....           | 3 13 2     | 5              | 5  | 10  |

The grazing returns are shown in detail in the next table. It is to be noted that for the first few years of the experiment not all the plots in respect of which grazing records were made were sown to lucerne, and in these cases the figures below represent the grazing provided by the natural growths on these plots. At most this affects the "third grazing year" plot for three years only, and the discrepancies thus introduced are unimportant. Here, again, the conventional value of .25 has been taken for the fallow grazing.

TABLE LI.—Showing Grazing Value, as Sheep per Acre for a Year, of Land Available for Stocking in Fallow-Wheat-Lucerne-Lucerne-Lucerne Rotation, 1914-1922.

| Year.                                        | Before Fallowing.     | Fallow.              | Wheat Stubble.      | First Grazing Year.   | Second Grazing Year. | Third Grazing Year.   | Total Grazing for 5 Years. |
|----------------------------------------------|-----------------------|----------------------|---------------------|-----------------------|----------------------|-----------------------|----------------------------|
| 1914 .....                                   | ·24                   | ·25                  | ·00                 | ·23                   | ·60                  | ·62                   | 1·94                       |

The net results of this rotation can now be stated in the usual form, allowing for costs of production at the rates previously adopted, and this is done in the next table. The cost of lucerne seeding is set down as 26s. 8d., reckoning seed worth 2s. 6d. per lb. and allowing 8d. per acre for broadcasting and 1s. for harrowing. The wheat crop received 2cwt. superphosphate.

TABLE LII.—Showing Gross and Net Monetary Returns from Fallow-Wheat-Lucerne-Lucerne-Lucerne Rotation, 1914-1922.

| Receipts—                                                       | Grain. |    |    | Hay. |    |    |

| Cost of production, wheat .....                                 | 2      | 14 | 6  | 2    | 14 | 6  |
| Cost of lucerne seeding .....                                   | 1      | 6  | 8  | 1    | 6  | 8  |
| Total expenditure per acre for 5 years                          | 6      | 11 | 2  | 6    | 11 | 2  |
| Balance of receipts over expenditure per acre for 5 years ..... | 2      | 1  | 11 | 3    | 14 | 7  |
| Net profit per acre per annum .....                             | 0      | 8  | 5  | 0    | 14 | 11 |

The net results of this rotation are thus represented by the figures 9s. 3d. and 15s. 10d., indicating the profit per acre when the wheat crop is treated as grain and hay respectively. These may next be compared with the corresponding figures recorded for other rotations. Fallow-wheat-pasture, when 2cwt. superphosphate was used with the wheat, gave net results represented by the figures 9s. 1d. and 13s. 5d. (paragraph (d)). In that case, however, the period covered was 12 years and included the relatively good seasons of 1911 and 1912. Referring back to the standard fallow-wheat rotation (paragraph (a)), and taking the same series of years (1914-1922), the corresponding figures are found to be 6s. 3d. and 14s. 6d. The rotation including three years of lucerne grazing following a wheat crop has thus given relatively good net results, and it is interesting to note that, with a much reduced outlay in cropping expenses as compared with other rotations quoted, net returns can be thus maintained at a satisfactory level provided the implied livestock values hold good.

(g) *Kale-Barley-Pease-Wheat*.—This was the last of a series of rotations of the type of the "Norfolk Four-course." Two others had been discontinued in 1914 as unsuited to local conditions and the series here dealt with ran from 1915 to 1922 with no more satisfactory results. Both cereal crops received  $\frac{1}{2}$ cwt. nitrate of soda along with the usual dressing of 1cwt. superphosphate. The kale was sown with  $\frac{1}{2}$ cwt. bonedust, and 10 tons per acre of farmyard manure was also applied with this crop. The pease received 1cwt. superphosphate.

The crop and grazing returns are shown in the usual way in the following tables:—

TABLE LIII.—*Showing Crop Returns from Kale-Barley-Pease-Wheat Rotation, 1915-1922.*

| 1920 .....                                   | 2.12           | .67             | 2.02           | .21            | 5.02                       |
| 1921 .....                                   | 1.79           | .69             | 2.29           | .77            | 5.54                       |
| 1922 .....                                   | 2.44           | .83             | 2.09           | .51            | 5.87                       |
| Means for 8 years                            | 2.49           | .66             | 2.05           | .39            | 5.59                       |
| Values at 12s. 6d. per sheep per annum ..... | s. d.<br>31 1½ | s. d.<br>8 3    | s. d.<br>25 7½ | s. d.<br>4 10½ | £ s. d.<br>3 9 10½         |

It will be seen that both wheat and barley mean returns are much below what may be regarded as profitable yields and the grazing returns are insufficient to make up the deficiencies.

Neither the kale nor the pease give returns equivalent to the costs of seeding these crops and the net results of the rotation is a substantial loss, as is shown in the next table. In this the cost of wheat growing on pea stubble is taken to be the same as that for barley (35s. per acre), and to each is added the cost of  $\frac{1}{2}$ cwt. nitrate of soda, 8s. 6d. The cost of putting in the kale (£3 9s. 9d.) is made up of the following items:—Ploughing, cultivation, and drilling, 11s. 6d.; 10 tons of farmyard manure, 50s.;  $\frac{1}{2}$ cwt. bonedust, 4s. 6d.; and seed (1½lbs.), 3s. 9d.

This is by far the most unsatisfactory set of results recorded in this section of the experiments. The defects in the plan of the rotation which have been chiefly responsible for its failure are, probably, firstly the omission of a period of fallow preceding the wheat crop, and secondly the heavy costs involved in the cultivation of fodder crops which, after all, have provided not a great deal more grazing than might be derived from the simple expedient of leaving cereal stubbles undisturbed for a year.

(h) *Fallow-Wheat-Barley and Fallow-Wheat-Oats* (New Series).—These rotations, commenced in 1924, have run for too short a period to allow of definite conclusions being drawn from the results recorded. Moreover, the period covered embraces two seasons (1927 and 1928) in which returns were abnormally low. The results, as far as they go, are shown, however, in the following tables.

 TABLE LVI.—*Showing Crop and Grazing Returns from Fallow-Wheat-Barley Rotation, 1924-28.*

|                        |                |    |     |        |    |    |        |      |                                                         |   |

The net return from the mean yields recorded in the two foregoing tables are summarised in the next table. As 2cwts. of superphosphate were applied at each seeding the corresponding allowance of 4s. 6d. has been made in the cost of production in each case. Otherwise the rates shown are those which have been used in previous tables.

Little can be said regarding these figures, except that the mean yields recorded, and, consequently, the net returns, are abnormally low; especially is this so with regard to the returns in the rotation including oats. There is, nevertheless, probably some significance in the fact that the rotation including barley has given better results than the other, and, even with the handicap of two abnormally poor seasons in five, a credit balance can still be shown on the basis of calculation adopted.

(i) *Fallow-Wheat-Barley-Grazing and Fallow-Wheat-Oats-Grazing (New Series).*—As with the previous pair of rotations little more can be done than record the actual returns for the five years' currency of these tests. Again 2cwts. superphosphate has been applied at each seeding.

The mean yields are again much below College Farm average returns for these crops, though in the oats series they are somewhat better than those recorded in the preceding paragraph. The value of grazing, moreover, in the pasture year exceeds the amount debited as rent for the year. After making calculations similar to those made in connection with Table LVIII., it will be seen that the barley series shows a small net profit, while the oats series is on the border line. The hay figures show a small profit and the grain figures a loss of the same amount.

(j) For the purpose of providing a concise statement of comparative net returns derived from the various rotations which have been introduced into the experiments, the figures which have been arrived at in the foregoing paragraphs as representing per acre profit or loss, are brought together in the concluding table of this report. As in the case of the summary of the manurial experiments, different periods are covered by different experiments. In order to provide as reliable a basis of comparison as possible, the returns recorded in the standard Fallow-Wheat rotation have been calculated for various periods, to correspond with those of other tests. It may be noted that the list includes two rotations, Fallow-Wheat-Pasture with dressings of ½wt. and 3cwts. superphosphate respectively, which have not been previously referred to in the report. The results recorded in these series of plots were not considered of sufficient interest to warrant their statement in detail, but the summary as represented by the figures quoted below is given to complete the record of the work which has been done.

TABLE LXII.—Summarising the Net Monetary Returns Per Acre from Land Worked Under Various Systems of Crop Rotation.

| Rotation.                                      | Period. | Annual Net Return per Acre over Whole Area. |                               |

(Concluded.)

## GREATER TRACTOR EFFICIENCY

The superiority of CROSS POWER KEROSENE is unquestioned when it is remembered that this high quality tractor fuel unfailingly provides:

Economy Quick Starting  
Full Power Less Carbon  
Low Consumption  
No Crankcase Dilution  
No Detonation Easy Idling

Used in conjunction with Cross Power Kerosene, GOLDEN SHELL OIL ensures easy and uninterrupted working, and longer life for the tractor, by successfully counteracting friction on all the moving parts in the machine.

## REPORT OF THE GOVERNMENT STATIST UPON THE LIVESTOCK STATISTICS OF SOUTH AUSTRALIA FOR THE YEAR 1929.

[By W. L. JOHNSTON, Government Statist.]

I.—*Sheep and Wool*.—1. *Number*.—The sheep flocks on December 31st, 1929, numbered 6,186,252 (7,079,947), decrease 893,695. These were classified as follows:—Ewes, 3,194,504 (3,637,147), decrease 442,643; wethers, 1,854,347 (2,042,651), decrease 188,304; rams, 90,057 (98,447); decrease, 8,390. Under one year old, 1,047,344 (1,301,702), decrease, 254,358.

2. *Breeds of Sheep*.—86.8 (89.9) per cent. of the flocks were returned as pure-bred Merino and 7.0 (5.4) per cent. as Merino Comebacks, 0.7 (0.6) per cent. as other pure breeds (Corriedale, Shropshire, Dorset Horn, Lincoln, Romney Marsh, Southdown, Suffolk, etc.), and the balance, 5.5 (4.1) per cent. were returned as Crossbreds.

3. *Lambing, 1929*.—During the year 1929 2,778,561 (2,918,594) ewes were mated and 1,231,710 (1,545,438) lambs marked, equal to a percentage of 44.33, compared with 52.95 for the previous year.

4. *Winter Lambing, 1930*.—2,407,000 ewes were reported as either mated or intended to be mated for the Winter Lambing of 1930. In addition, 218,000 ewes were expected to be reserved for Spring Lambing.

5. *Wool Clip*.—6,617,986 (7,247,099) sheep and lambs were shorn, the total clip, including locks, bellies, pieces, &c., being 56,083,898 (63,729,419) lbs., being a decrease of 7,645,521 lbs. The average weight of fleece for sheep and lambs combined was 8.47 (8.79) and for sheep only 9.59 (10.10) lbs.

6. *Total Wool Production*.—Subject to slight revision of fellmongered wool, it is estimated that the grand total wool production, including the clip and wool fellmongered and wool on local skins exported, was 67,300,881 (74,616,004) lbs.; decrease, 7,315,123 lbs.; value, £2,549,021 (£4,654,172); decrease, £2,105,151, the average value per lb. greasy being 9.09d. (14.97d.).

II. *Cattle*.—All kinds, 204,516 (263,016); decrease, 58,500. Dairying cattle, 104,255 (108,969); decrease, 4,714; classified as follows:—In milk 75,574 (76,147), dry 21,219 (24,998), and heifers, springing, 7,462 (7,824). In addition there were 11,726 (10,598) other heifers, one year and over, which are not included in the dairying total, but which are possible additions to the dairying herds.

III. *Horses*.—189,054 (205,865).

IV. *Pigs*.—74,906 (62,723).

V. *Goyder's Line of Rainfall and Livestock*.—During the year 1929 the percentage to the total of sheep outside Goyder's Line of Rainfall fell from 36.50 to 26.48: Cattle 41.87 to 27.02, and Horses 27.44 to 24.89. The numbers within and without the line for 1929 were: Sheep 4,548,246 and 1,638,006, Cattle 149,246 and 55,270, Horses 141,992 and 47,062.

VI. *Interstate Movement by Land of Stock*.—The State gained 39,970 head of Cattle and 299,800 Sheep, and lost 2,552 Horses by transit of stock between States. The total interstate imports were: Sheep 402,348, Cattle 43,592, Horses 910, and exports were: Sheep 102,548, Cattle, 3,622, and Horses 3,462. Net exports of Horses to overseas countries 635.

VII. *Slaughtering*.—Sheep and Lambs 1,242,835 (1,263,352), decrease 20,517, for export 1,568 (32,239); Cattle 117,806 (127,627), decrease 9,821; Pigs 96,449 (98,679), decrease 2,230.

VIII. *Top-dressed Pasture Lands*.—There was an increase during the year of 51,701 acres in the area top-dressed, and of 2,672 tons in the manure used. The respective totals were 302,114 (250,413) acres, Manure used 15,701 (13,029) tons. In addition there were 49,701 acres of pastures previously top-dressed, but not during 1929.

## 1. LIVESTOCK AS AT DECEMBER 31st, 1929, IN COMPARISON WITH DECEMBER 31st, 1928.

\* Minus sign (—) denotes decrease.

## ANNUAL REPORT ON PASTURE IMPROVEMENT, KYBYBOLITE. 1929-30.

[By L. J. COOK, R.D.A., Manager.]

The season from a pasture point of view was very good, results secured from some pastures exceeding those of recent seasons, whilst a number of plots yielded record returns in grazing. Plants received a really good start in the Autumn, and had very little check throughout their growing periods. On account of the light Spring rains, however, they did not finish quite as well as of recent years, and this factor spoilt what promised to be an all round record grazing season.

A useful rain was received in January, 1929, but the February and March rains were light, considerably below average. April, however, opened with splendid falls, and record rains were recorded for the month, followed by average falls in May, June, and July. Thus plants were able to make good early growth, and well establish their root systems before cold soil conditions were evident, so that comparatively good feed was available throughout the whole of Winter. Some fairly heavy frosts were recorded during June, but these helped rather than checked grasses and clovers, as they decidedly checked growths of Capeweed that were becoming rather strong in some fields. The rains of August, September, October, and November were all below average so that although the Spring development of pastures was good, they were not as great, or complete as usual. Especially was this noticed on pastures that were grazed to their maximum during Winter and early Spring. Summer rains were light, and consequently there was a longer absence of green picking this summer. The usual summer growth from rooted grasses and plants, such as cat's ear, were poor.

The following table shows the monthly rainfall of recent years, compared with the average for the past 24 seasons:—

|                 | 1926.<br>In. | 1927.<br>In. | 1928.<br>In. | 1929.<br>In. | 1906-29.<br>In. |

### THE IMPROVEMENT OF NATURAL PASTURES WITHOUT CULTIVATION.

The work of topdressing natural pastures with phosphatic fertilisers and lime was commenced during 1919, additional plots were started during 1924 and 1926, and a further four were added this season, 1929, to supplement the work being carried out in conjunction with the Waite Research Institute. At present there are 17 plots being utilised for this work, 13 of which are 3½ acres in area, and four are 5 acres each.

Since 1921 careful records of the grazing secured from the plots have been kept. This season the plots have been continuously grazed in rotation by five flocks, constituted according to the estimated carrying capacity, and a separate flock has been used for each type of fertilised pasture. That is A and AA flocks, 20 sheep, have been used

## FRUIT TREES

### ONE GROWER SAYS—

"The trees (750) arrived in excellent order and are of exceptional quality. Our local inspector said they were the best trees he had seen. You will get my order, about same number, for next year."

on unmanured land, 24 acres. B flock of 36 sheep has been used on 14 acres of land improved with superphosphate; C flock of 48 sheep has been used on 17 acres of land improved with lime and superphosphate; whilst D flock of 20 sheep has been used on 10½ acres of land improved with rock phosphates. Similar type and aged sheep have been used in each flock. Through the kind help of the Waite Research Institute we have been able to weigh these sheep monthly, and it is anticipated that some very useful and interesting additional figures will be available in the future.

The following table shows the fertiliser applied, with date, and rate of applications, whilst Table 3 shows the grazing results secured:—

TABLE 2.—*Fertilising of Natural Grazing Test, Kybybolite, 1919-29.*

| Plot. | Total Fertiliser per Acre.                                                                                                                                            | Date and Rate of Application.                                                  |

| Increase above phosphate dressed plots— | —                          | —       | 1.17    | —       | —       | —       | —       | —       | 0.07    | 0.46     | —        | —        | 0.53     |

In commenting on the above results, it is necessary to state that although all plots were grazed as uniformly as possible, they were not completely grazed throughout the season, and a lot of feed was still available at the close of the grazing year, March 31st, 1930. The season for this class of pasture was comparatively good, and the feed

produced was greater than the flocks required. However, this extra feed will be required and utilised by the flocks during April and May, 1930, and will appear in the results for the coming season.

In comparing the six plots that have now provided results for nine consecutive seasons, the four dressed with phosphatic fertiliser only, have increased the carrying capacity approximately 1 sheep per acre, or 117 per cent. above that of the check plot; whilst the lime and phosphate dressed plot has increased 2.15 sheep per acre, or 256 per cent. above the No Manure Plot, and 1.17 sheep per acre, or 119 per cent. above the phosphate only dressed plots.

We have not been successful in our endeavors to secure a further supply of aluminium rock phosphate, consequently Plot No. 1, which was due for a further application this year, is feeling the need of more fertiliser, as shown by the low carrying capacity of 1.11 sheep per acre.

The addition of a small quantity of water soluble phosphate to Plot No. 2 is continuing to give an increased carrying capacity, and although of recent years this plot has only received half the quantity of phosphoric acid that has been given to Plot No. 4, its growth of pasture has been better. This result has possibly been helped by the mild winters, the wetter seasons being more helpful in dissolving the phosphorus contained in rock phosphate.

In considering Plots Nos. 7, 10, 11, and 12 from which five seasons' grazings have now been obtained, we find that No. 7, dressed with water soluble phosphate, has increased the carrying capacity 1.04 sheep per acre, or 118 per cent. on that of the check plot No. 12. Plot No. 11, dressed with citrate and acid soluble phosphate, has increased 0.89 sheep per acre, or 101 per cent.; whilst Plot No. 10, dressed with lime as well as water soluble phosphate, has increased 1.42 sheep per acre, or 161 per cent. above No Manure, and 0.38 sheep, or 20 per cent. above No. 7, the water soluble phosphate dressed plot.

In comparing Plots Nos. 8, 9, 12, and 13, from which four seasons' grazing are available, we find that Plot 8, dressed with water soluble phosphate, has increased 0.80 sheep per acre, or 88 per cent. on the check plot. Plot No. 9, dressed with gypsum and water soluble phosphate, has increased 0.73 sheep per acre, or 81 per cent.; and Plot No. 13, dressed with crushed limestone and water soluble phosphate, has increased 1.33 sheep per acre, or 148 per cent. on the No Manure Plot.

The gypsum, therefore, has not shown quite equal to the phosphate only plot, whereas the crushed limestone has so far shown an increase above the latter of 0.53 sheep per acre, or 31 per cent.

One important factor showing is the gradual improving effect of fertilisers on the natural pastures. For instance, plots dressed with water soluble phosphate the first year of application increase the yield 34 per cent.; the first two years the increase is 53 per cent.; the first three years it is 84 per cent.; the first four years it is 115 per cent.; whilst the first five years it shows at 118 per cent., showing clearly that to secure success from topdressing with water soluble phosphates annual application should be given continuously.

On account of the varying dates of commencing plots it is difficult as yet to get an even result of the various forms of fertiliser, but by comparing the averages of all plots for the past four seasons a reasonable comparison can be shown, as follows:—

Check plots have carried 0.81 sheep per acre.

Water soluble phosphate plots have carried 1.91 sheep per acre, or 136 per cent. increase over No Manure.

Citrate soluble phosphate plot has carried 1.89 sheep per acre, or 133 per cent. increase over No Manure.

Acid soluble phosphate plots have carried 1.77 sheep per acre, or 119 per cent. increase over No Manure.

Lime and water soluble phosphate plots have carried 2.84 sheep per acre, or 251 per cent. increase over No Manure, and 49 per cent. increase over water soluble phosphate.

Limestone and water soluble phosphate plot has carried 2.23 sheep per acre, or 175 per cent. increase over No Manure, and 17 per cent. increase over water soluble phosphate.

Gypsum and water soluble phosphate plot has carried 1.63 sheep per acre, or 101 per cent. over No Manure.

### SOWN PASTURES.

#### SUBTERRANEAN CLOVER AND WIMMERA RYE GRASS.

The 15 plots of this pasture mixture, established during 1924, are being maintained and fully grazed each season. This year they were again grazed monthly in rotation, using 200 ewes, divided into four flocks, on the 70 acres of plots. General grazing was commenced early in May, and continued incessantly until March 31st, 1930, when the bulk of the feed on the plots was consumed, although sufficient was still available to carry the ewes through April until the new season's feed had developed. Rye grass was still prominent, especially during the winter months, on plots that have been well fertilised with phosphates, and Subterranean Clover made good growth, although some of the plots did not finish as well as they have done in recent years. Particularly was this the case with plots fertilised with acid soluble phosphate.

The following table shows the fertiliser given to the various plots, with rate and time of application, together with the grazing results for the past five seasons, from the plots individually, and from the 70½ acres collectively.

TABLE 4.—Fertiliser Test on Subterranean Clover and Wimmera Rye Grass, Kybybolite. 1925-30.

In commenting on the above table, it is to be noted that some very high yields have been received. Plot 5, in carrying 5.37 sheep per acre, is a sheep to the acre better than any previous result obtained. This plot has received a dressing of 180lbs. 45 per cent. superphosphate during each of the last two Autumns, and has been the most productive plot for both years. Plots Nos. 4 and 7 also gave very fine results, with 4.52 sheep per acre each; whilst Nos. 3 and 15 were almost as good with 4.40 and 4.32 sheep respectively. All of these plots have been fertilised with superphosphate, whilst Nos. 7 and 3 have received lime and gypsum as well. Plot No. 8, dressed with Ephos phosphate, with 3.77 sheep per acre, also yielded well above the average.

For five seasons Plot No. 15, dressed with 1cwt. 45 per cent. superphosphate annually, has given the greatest result, having averaged 3.95 sheep per acre for the whole period. Plot 8, a most consistent yielder, is second, with 3.74 sheep per acre, and Plot 7, dressed with lime and superphosphate, is close up with an average of 3.70 sheep.

The average results of the principal plots are compared below in order of merit.

|    |                                                                                              | Increase above no<br>manure. |                 |           |

#### SUBTERRANEAN CLOVER.

A number of comparatively large fields have now been established for some years with Subterranean Clover, and a few with Wimmera Rye Grass included.

Manurial dressings have been phosphatic, and some of the fields have been limed in the past. The grazing of fields has not been complete in every case, as certain fields have necessarily had to be reserved for late Autumn feed each season, but the following table shows the grazing taken from these fields during the last six seasons, and is of interest when compared with other forms of pasture.

TABLE 5.—Subterranean Clover Grazing, Kybybolite, 1924-30.

| Season.       | No. of<br>Fields. | Area.<br>Acres. | Total Feed<br>Days. | Sheep per<br>Acre. |

|               |                   | 1,083.17        | 934,388             | 2.36               |

#### RYE GRASSES AND ALSIKE CLOVER.

Trials with both Perennial and Italian Rye Grasses with Alsike Clover have been continued in the six-course rotation of two-acre fields, and of recent years better results have been obtained from Perennial Rye than from the Italian. We now have seven

seasons' results, which are shown in the accompanying table, and so far the results gained have not been outstanding. Except that some advantage is available through having a quick response from summer rains, the yearly grazing results are not as good as those obtained from ordinary arable land left out for grass, and top dressed.

TABLE 6.—*Grazing of Rye Grasses and Alsike Clover, Kybybolite, 1923-30.*

|              |              | 29.10           | 16,860               | 1.59               |

In handling the above pasture, it has been treated purely as a temporary pasture of two, and a few cases of three, seasons' duration, and it is to be noted that its average on its first year's grazing for seven seasons has been 1.38 sheep per acre. On its second year's grazing for six seasons its average has been 1.67 sheep. Twice it has been left for a third season, when its average has been 2.02 sheep per acre.

#### TOP DRESSING OLD CULTIVATED LAND.

For the past five years fair areas of land, that have been cultivated for a period of from 15 to 20 years, have been left out of the cropping areas, and to enhance their grazing they have been topdressed annually with 1cwt. superphosphate per acre, but no grasses or clovers have been sown. This has had the effect of greatly increasing the growths of naturalised grasses and clovers. The following table summarises the grazing received from this class of pasture each year:—

TABLE 7.—*Grazing of Top-Dressed Old Cultivated Land, Kybybolite, 1925-30.*

| Season.       | No. of Fields. | Area.<br>Acres. | Total Feed<br>Days. | Sheep per Acre. |
|---------------|----------------|-----------------|---------------------|-----------------|
| 1925-26 ..... | 1              | 50.00           | 30,097              | 1.65            |
| 1926-27 ..... | 4              | 140.47          | 68,764              | 1.34            |
| 1927-28 ..... | 3              | 102.47          | 76,196              | 2.04            |
| 1928-29 ..... | 3              | 121.07          | 102,089             | 2.31            |
| 1929-30 ..... | 4              | 151.83          | 144,242             | 2.60            |
|               |                | 565.84          | 421,488             | 2.04            |

Similar land left out of cultivation, but not topdressed, has during the past two seasons only carried 1.10 sheep per acre.

As a comparison to the above, the following two tables are included to show the grazing received from similar land that has never been cultivated.

Table 8 shows the combined results of all such land that has been topdressed, whilst Table 9 shows the results from a fair area of unimproved natural land—that is, land that has neither been cultivated or topdressed.

TABLE 8.—*Grazing of Improved Natural Land by Topdressing Only, Kybybolite, 1921-30.*

| Season.       | No. of Plots. | Area.<br>Acres. | Total Feed<br>Days. | Sheep per Acre. |
|---------------|---------------|-----------------|---------------------|-----------------|

In summarising the grazing results of the Farm, the areas under the different treatments have been collected, and averaged over the various periods during which they have been in use, and are tabulated as follows:—

TABLE 10.—*Summary of Grazing Results at Kybybolite.*

| Type of Grazing.                               | No. of<br>Years<br>Tested. | Area.<br>Acres. | Sheep<br>per<br>Acre<br>per<br>Annum. | Increase Over<br>No Manure.<br>Sheep. Per cent. |
|------------------------------------------------|----------------------------|-----------------|---------------------------------------|-------------------------------------------------|
| 1. Subt. Clover and Wimmera Rye Grass (expl.)  | 5                          | 70.5            | 3.13                                  | 2.45                                            |
| 2. Subt. Clover (large fields) .....           | 6                          | 180.53          | 2.36                                  | 1.68                                            |
| 3. Topdressed old cultivated land .....        | 5                          | 113.17          | 2.04                                  | 1.36                                            |
| 4. Improved Natural Land (topdressing only) .. | 9                          | 31.11           | 2.00                                  | 1.32                                            |
| 5. Rye Grass and Alsike Clover .....           | 7                          | 4.16            | 1.59                                  | 0.91                                            |
| 6. Crimson and other Annual Clovers .....      | 8                          | 9.48            | 1.44                                  | 0.76                                            |
| 7. Non-topdressed old cultivated land .....    | 2                          | 75.49           | 1.10                                  | 0.42                                            |
| 8. Improved natural land .....                 | 9                          | 76.44           | 0.68                                  | —                                               |

The above results can be looked upon as a fair comparison, although it must be noted that it has not been practical to fully graze all the larger fields, especially amongst those in items 2, 3, and 7. However, as they are averaged over a number of seasons, the table is useful and interesting, and shows the advantages to be gained from Subterranean Clover, Wimmera Rye Grass, and topdressing with phosphates.

#### SOWN WINTER GRASSES.

Three additional five-acre plots have been established this year, one each with Wimmera Rye Grass, Perennial Rye Grass, and *Phalaris minor*. These, with *Phalaris bulbosa*, have so far given best promise in small plots towards producing Winter feed, and were established on well-prepared virgin fallow land. Good stands were obtained by sowing 8lbs. seed per acre for the Rye Grasses and 2lbs. *Phalaris minor*, with 1cwt. 45 per cent. superphosphate per acre.

It is anticipated to also establish a plot with *Phalaris bulbosa*, fence the plots, and secure grazing figures of these grasses in future seasons.

#### NITROGEN FERTILISER TEST.

Further work has been commenced in conjunction with the Nitrogen Fertilisers Limited, to test the complete fertilisation of Subterranean Clover and Rye Grass pasture,

combined with intensive grazing by the milking herd. Two four-acre plots were established late this year, and six more are being prepared for the coming season. They will all be well manured with phosphates, and half will be given nitrogen fertiliser as well, with the idea mainly of increasing the winter growths and, if possible, extending the growing period of the pastures. Of the two plots established this year, the one dressed with lewt of sulphate of ammonia per acre in August gave an immediate response in increased growth of grasses present.

# VEITCH EXPERIMENTAL FARM HARVEST REPORT, 1929.

[By R. C. SOOTT, Supervisor of Experimental Work, and L. SMITH, Manager.]

This farm is situated in the Northern Murray Mallee lands, and, in common with other farms in the district, has yielded very low returns, owing to the extremely dry conditions experienced.

For the benefit of those not familiar with the location, it may be stated that Veitch is portion of the Hundred of Allen, and lies about 16 miles South of Loxton.

The experimental farm comprises 3,800 acres, of which about 2,500 are cleared and available for cultivation. Approximately 600 acres are as yet uncleared, whilst the balance consists of such poor sandy soil, subject to drift, that it is not considered wise to remove the natural scrub.

The bulk of the land is of a sandy nature, varying from light sand to shallow loam, with coarse calcareous soils overlying hard limestone rock.

## THE SEASON.

This is the third extremely dry season in succession, and examination of the rainfall tables submitted below will indicate the conditions with which farmers have had to contend.

The fallows on which the 1929 crops were sown received practically no rain. From August, 1928, to April, 1929, only 2.56in. were recorded, whilst normally fallows benefit to the extent of rather more than 8in. during this period. Consequently they did not receive the usual amount of tillage and were not as well compacted as desired. In this district April and May are the best seeding months, but the former was practically rainless, whilst in the latter only 44 points were registered. Seeding, therefore, extended well into June. Notwithstanding these conditions the grain germinated satisfactorily, and with a favorable spring, normal yields were possible. However, the falls in succeeding months were below the average, and combined with frequent winds, allowed sand movement to repeatedly cut off the young growing plants. Except where the crops were protected by belts of timber they were completely destroyed. Whilst the lack of moisture affected the development of plants, there is little doubt that the greatest factor in causing a total failure in much of our Northern Murray Mallee land was this cutting action of moving sand. Where this action was prevented, light yields were harvested.

*Distribution of "Useful" Rainfall.*

|                                 | 1924. | 1925. | 1926. | 1927. | 1928. | 1929. | Means,<br>1909-1929. |
|---------------------------------|-------|-------|-------|-------|-------|-------|----------------------|
|                                 | Ins.  | Ins.  | Ins.  | Ins.  | Ins.  | Ins.  | Ins.                 |
| Seeding rains (April-May) . . . | 0.94  | 3.16  | 4.59  | 0.54  | 0.38  | 0.48  | 1.84                 |
| Winter rains (June-July) . . .  | 1.62  | 1.38  | 2.00  | 1.53  | 1.96  | 0.88  | 2.34                 |
| Spring rains (Aug.-Oct.) . . .  | 4.04  | 2.10  | 4.42  | 2.25  | 1.72  | 1.59  | 3.78                 |
| Early Summer rains (Nov.) ..    | 1.37  | 0.11  | 0.00  | 0.34  | 0.04  | 0.59  | 0.74                 |
| Total "Useful" . . .            | 7.97  | 6.75  | 11.01 | 4.66  | 4.10  | 3.54  | 8.70                 |

The total for the year is 7.32in., but approximately 3in. fell shortly after Christmas, and was of no benefit to crops. This is the third lowest total in our records, the other extremely dry seasons being 1927, 5.94in., and 1914, 6.24in.

The average annual registration is 11.83in., and, therefore, the fall for 1929 is 4½in. below the mean.

The rainfall received between the months of April and November is regarded as being of direct benefit to the wheat crop, and is shown in the table termed "Useful" Rainfall. The quantity falling on the 1929 crops is seen to be only slightly over 3½in. This is the lowest amount recorded, followed by 1914, in which 3.66in. were registered. It is obvious that such a small quantity spread over eight months can be of practically no benefit to crops.

How unfavorable the agricultural conditions have proved is indicated by the rainfall records for the past three seasons.

The total rainfall for the years 1927, 1928, and 1929 has been 5.94in., 8.94in., and 7.32in. respectively, and the "useful" fall 4.66in., 4.10in., and 3.54in.

**HAY CROPS.**

In all, 110 acres were sown for hay, but the crops did not make sufficient growth for binding, and were fed off. Including a total failure for this season, the mean hay yield for the 1910-1929 period is 0 tons 19cwts. 41lbs.

**OAT CROPS.**

The oat crops were a complete failure, and an area of 57 acres was fed off. The oat average for the past 14 seasons amounts to 12bush. 22lbs.

**BARLEY CROPS.**

The barley made fair growth considering the character of the season, but failed to form grain. Barley has been grown on this farm since 1915, and the mean yield is 13bush. 21lbs.

**WHEAT CROPS.**

An area of 554.25 acres was sown to wheat at the rate of 1bush. of seed and 84lbs. 45 grade superphosphate per acre. However, 230 acres sown in Field Nos. 3A, 4, 7, and 11 failed entirely, and were not harvested. Of the balance, much was not worth reaping, but the machines were run over any areas yielding grain. The best patches were those protected from the action of drift sand, and these yielded up to about 4bush. per acre. The average for the area harvested was approximately 1bush.

It was not possible to obtain yields of varieties, but the most hardy appeared to be Sultan and King's White. In all 302bush. 35lbs. of wheat were secured, or an average of 38lbs. from an area of 554.25 acres.

In the following table the wheat averages since 1909 are shown:—

*Wheat Returns—Veitch, 1909-29.*

| Year.      | Total<br>Rainfall | "Useful"<br>Rainfall. | Area.    | Total<br>Yield. | Yield<br>per Acre. |

| 1928 ....  | 8.94              | 4.10                  | 474.64   | 1,513 29        | 3 12               |
| 1929 ....  | 7.32              | 3.54                  | 554.25   | 302 35          | 0 33               |
| Means .... | 11.83             | 8.70                  | 9,783.17 | 87,672 45       | 8 58               |

The lowest return in our records is that secured in 1914, when the "Useful" rainfall totalled only 3.66in. and the wheat yield 21lbs. The results for the past season are very similar, as the "Useful" rainfall amounts to 3.54in. and the wheat average 33lbs. per acre. The best wheat years recorded are 1920 and 1909, with yields of 22bush. 12lbs. and 18bush. respectively, whilst the mean return for the past 21 years is 8bush. 58lbs. per acre.

## AGRICULTURAL EXPERIMENTS AT INMAN VALLEY.

[By R. C. SCOTT, Supervisor of Experimental Work, and A. L. WARREN, Field Officer.]

(Conducted on the property of Mr. A. M. FULLER.)

At the request of the Port Elliot Branch of the Agricultural Bureau, Pasture Experiments were commenced at Inman Valley in 1928. Since that date the residents of Inman Valley have re-formed a local Branch of the Bureau, and these plots are now conducted under the joint interest of both Branches.

Mr. A. M. Fuller agreed to carry out the experiments on his property, situated about 12 miles from Victor Harbor on the Yankalilla Road. The site selected comprises 15 acres of flat land lying on the north side of the River Inman. Prior to purchase by Mr. Fuller, this land had received very little manure, and at the commencement of the tests was in a comparatively low state of fertility.

The soil varies considerably. Adjoining the river it consists of coarse sandy material which dries out rapidly, whilst at the foot of the hills it is of a black heavy nature.

During the past two years, rainfall records have been kept, but as there is no official gauge at Inman Valley, mean figures for the district are not available. However, it is generally considered that the registrations for Myponga, some nine miles north, most nearly approach those secured at Inman Valley.

In the following table, the rainfall, month by month, for the years 1928 and 1929 is shown comparatively with the mean fall for Myponga for the past 36 years:—

|                 | INMAN VALLEY. |               | MYPONGA.                 |
|-----------------|---------------|---------------|--------------------------|

| September ..... | 2.15          | 4.44          | 3.62                     |
| October .....   | 4.21          | 2.06          | 2.15                     |
| November .....  | 1.04          | 0.96          | 1.49                     |
| December .....  | 0.54          | 1.36          | 1.17                     |
| Total .....     | <u>29.54</u>  | <u>28.51</u>  | <u>29.14</u>             |

The total rainfall at Inman Valley for the two seasons was approximately equal to the average.

June and July of 1928 were exceptionally wet, almost 11½ in. being registered in these two months. On the other hand, the summer was extremely dry. From the first week in November till the end of February, 1929, only 132 points of rain fell. This long, dry period caused the death of many young plants which had not become sufficiently established to withstand such conditions.

During the past season, June, July, and August were wet and frosty with the result that plant growth was retarded. The rainfall in succeeding months was satisfactory, and good pasture was secured in Spring and early Summer.

### PLAN OF EXPERIMENT.

The experiments consist of tests with varieties, pure stands, and pasture mixtures. The latter are sown in fenced plots, and grazing records secured. The plots of pure stands were seeded this season and consist of two varieties of grass which promise well for the district, each being sown on an area of approximately three-quarters of an acre.

The pasture variety tests comprise a collection of grasses and clovers considered likely to prove of value, being seeded separately in plots about a seventh of an acre in area. All experiments have received an annual dressing of 2cwts. 45 grade Superphosphate per acre. This season Nitrogen Fertilisers Pty., Ltd., desired to test the influence of applications of Nitrogen to pasture land, and it was agreed that the experiment could be conducted on these plots. Accordingly, a strip across each field was dressed with 1cwt. of Sulphate of Ammonia per acre during the first two days of May, and on Plot 2 a further cwt. is to be applied in Spring.

The fertiliser was supplied by the above company. The area so treated has not been fenced off from the main plot, no attempt being made to measure the benefit by the stock-carrying capacity. In order to allow the effect to be clearly noted, quadrats have been placed on the respective plots, thus protecting the enclosed area from stock. The growth of fodder from each treatment can then be compared in addition to any general advantages that are apparent.

### PLOT 1.

This Plot is 4.45 acres in area. At the northern end the soil is of heavy black nature with lighter sandy land on the southern side. It was seeded early in May, 1928, with the following mixture:—

|                               | Lbs. Per Acre. |
|-------------------------------|----------------|
| Perennial Rye Grass . . . . . | 12             |
| Italian Rye Grass . . . . .   | 6              |
| White Clover . . . . .        | 4              |

Germination was satisfactory, but a dry spell toward the end of May destroyed plants in those patches where the land was not of fine tilth. These patches were re-seeded during the first week of June. Lucerne flea checked the clover, and as many plants failed to survive the long, dry summer, it was decided to seed again in 1929. The seed applied was:—

|                                           | Lbs. Per Acre. |
|-------------------------------------------|----------------|
| Poverty Bay Perennial Rye Grass . . . . . | 10             |
| Wimmera Rye Grass . . . . .               | 10             |
| White Clover . . . . .                    | $\frac{2}{1}$  |
| Alsike Clover . . . . .                   | 1              |

Seeding was done on April 23rd by means of a drill. This implement was utilised so as not to disturb the plants already present. A good germination resulted, but as was the case in the previous year, the clover suffered from lucerne flea attack.

A very satisfactory stand has now been obtained, which should provide increased grazing in future years. Record has been kept of the number of stock pastured and the amount of fodder produced is calculated according to the sheep-carrying capacity.

As sheep, cattle, and horses have been grazed it is necessary to reduce all animals to the equivalent of sheep. A horse has been regarded as consuming an amount of fodder equal to 10 sheep, and cattle and light horses an amount equal to eight sheep. On this basis the plot yielded pasture for 1.43 sheep per acre in 1928, and for 2.89 sheep in 1929. It is anticipated that these grazing results will be considerably increased in future years.

## PLOT 2.

This field is larger than the preceding plot, being 7.18 acres in area, and contains a rather higher percentage of sandy soil. The seed sown in 1928 was as follows:—

|                                  | Lbs. Per Acre. |
|----------------------------------|----------------|
| Cocksfoot .. . . .               | 7              |
| Meadow Fescue .. . . .           | 6              |
| <i>Phalaris bulbosa</i> .. . . . | 2              |
| Timothy .. . . .                 | 2              |
| White Clover .. . . .            | 4              |
| Strawberry Clover .. . . .       | 1              |
| Perennial Red Clover .. . . .    | 1              |

With the exception of Meadow Fescue and Timothy, the seed germinated well. Here again lucerne flea and dry Summer weather affected development. In order to thicken up the stand, a further mixture was drilled in on April 24th, 1929, consisting of:—

|                            | Lbs. per Acre. |
|----------------------------|----------------|
| Cocksfoot .. . . .         | 5              |
| Sheeps Burnet .. . . .     | 3              |
| Chicory .. . . .           | 1              |
| White Clover .. . . .      | 3              |
| Strawberry Clover .. . . . | 2              |

The weather conditions following this seeding proved favorable, and a considerable improvement in pasturage resulted. Amongst the grasses *Phalaris bulbosa* and Cocksfoot have done really well, and there is also a fair sprinkling of Sheeps Burnet. The clovers suffered as a result of the lucerne flea, but are present and promise increased growth this season. On the heavier land Strawberry Clover has become well established and is yielding good grazing. Observations on the plot indicate that close attention must be given to the sheep grazing of Cocksfoot planted on light land. It was noted that if left on too long they pull up a large percentage of plants, thus rapidly destroying the pasture. On the heavier and tighter soil the damage is not nearly so severe.

The grazing records show the carrying capacity of this plot to have been 1.11 and 2.14 sheep per acre for seasons 1928 and 1929 respectively.

The outstanding fodder has been *Phalaris bulbosa*, and in order to still further improve the pasture in this plot, 2lbs. of seed per acre of this grass was drilled in this year. Germination has been fairly good, and we now have a satisfactory pasture field.

## PLOT 3.

For the purpose of testing pure stands of the two grasses showing most promise for the Inman Valley district, a further area was seeded in 1930 with *Phalaris bulbosa* and Perennial Rye Grass. The whole field covers approximately 1½ acres, and is equally divided between the two varieties.

On the whole, the soil is a rich dark-colored river flat which, during the last two seasons, has carried a potato crop.

At the end of May the land was well cultivated and manured with 3cwts. 45 grade Superphosphate per acre. In addition, a portion received an application of 1cwt. Sulphate of Ammonia per acre.

On June 3rd half the plot was sown with Perennial Rye Grass at the rate of 30lbs. per acre, and the remaining half with *Phalaris bulbosa* at 8lbs. per acre. Both varieties have germinated well, and interesting results are anticipated.

## VARIETY PLOTS.

In all 20 pasture varieties are undergoing tests in plots about 1½ square chains in area. Every year they have received a dressing of 2cwts. 45 grade Superphosphate, and grazed as required.

*Perennial Rye Grass*.—Made good growth at first, but, being sown on light land adjoining the river, did not survive the dry Summer. This pasture has since been resown on heavier land.

*Wimmera Rye Grass*.—Has made satisfactory growth, and re-seeded itself fairly well.

*Cocksfoot*.—Thinned out by the dry Summer, but promises to be one of our best grasses.

*Meadow Fescue*.—Thin germination and has made poor growth. Plot abandoned.  
*Phalaris bulbosa*.—The outstanding pasture in this experiment. Rather a thin stand in the first year, but has thickened up wonderfully. Is eaten readily by stock, and remains fresh throughout the Summer.

*Timothy*.—Germinated fairly well, but died out in the Summer. Plot abandoned.

*Crested Dogstail*.—Made fair growth, but retarded by Summer conditions. Abandoned.

*Meadow Foxtail*.—Complete failure. Abandoned.

*Danthonia pilosa*.—Very little growth to be seen in the first season. In latter years has developed well and yielded good grazing.

*Sheeps Burnet*.—A good drought resistant fodder, showing promise.

*Chicory*.—Germinated well, and has made good growth in the Summer months. Eaten readily by stock.

*Sulla*.—Fair growth at first, but later died right out. Abandoned.

*Lucerne*.—Absolutely destroyed by lucerne flea.

*White Clover*.—So severely damaged by flea that plot had to be abandoned.

*Alsike Clover*.—Recovered from flea attack, and has made fairly good growth.

*Perennial Red Clover*.—Suffered little damage from flea, but died out rapidly.

*Bokhara Melilot*.—Made practically no growth, and is apparently of little value here.

*Subterranean Clover*.—Attacked by flea, but later made splendid growth, and now provides a good stand.

*Clustered Clover*.—A useful variety which has done well. Eaten readily by stock.

*Strawberry Clover*.—Planted on heavy wet land. Germinated well and spreading rapidly. Particularly relished by stock.

#### GENERAL REMARKS.

Having experienced two seasons with abnormal weather characteristics, it has taken some time to establish these pastures. It is anticipated that satisfactory yields will be secured in the future and information of value to the district obtained.

The evidence accumulated indicates that the establishing of clover pastures is very difficult, owing to the presence of lucerne flea. The best clover appears to be Subterranean, followed by Clustered, Strawberry, and Alsike.

Amongst the grasses, *Phalaris bulbosa* is outstanding, and the seeding of this pasture can be confidently recommended. Perennial Rye Grass, Wimmera Eye Grass, and Cocksfoot have also done well, whilst Sheeps Burnet and Chicory can be included amongst the fodders showing value in this district.

We are glad to have the opportunity of expressing our appreciation of the manner in which Mr. Fuller has co-operated with the Department in these experiments. He has maintained a very keen interest in the work, kept careful records, and undertaken all operations in a thoroughly efficient manner. To the local Agricultural Bureau also we express our thanks for organising annual visits of inspection to the plots.

## TOMATO DISEASES IN SOUTH AUSTRALIA AND HOW TO CONTROL THEM

with special reference to Glasshouse Tomato Culture.

---

[By GEOFFREY SAMUEL, M.Sc., Plant Pathologist, Waite Agricultural  
Research Institute, University of Adelaide.]

---

### INTRODUCTION.

Both outdoor and glasshouse tomatoes are now grown extensively round Adelaide. There is only one serious disease of the outdoor crop, and that is the Australian Spotted Wilt disease, commonly called just "tomato wilt." This disease becomes epidemic in certain seasons and destroys tomato plants by the tens of thousands. In suburban gardens on the Adelaide plains it is present every year, and many home gardeners have given up trying to grow tomatoes because of the disease.

In recent years there has been a rapid increase in the number of glasshouse tomatoes grown, however, mainly because of the high prices obtained for early fruit on the Melbourne market. The mild winter climate on the Adelaide plains enables the plants to be grown in unheated glasshouses, and owing to the simple type of construction employed houses can be erected at a comparatively small capital cost. The result has been that quite a considerable number of tomatoes are produced by growers who have put up a few houses "as a sideline," and who combine tomato growing with other gardening. At the same time there is an increasing number of growers who are devoting practically the whole of their energy to tomato growing, and who raise anything from 4,000 to 40,000 or more plants every year under glass.

Owing to the different conditions and the more intensive cultivation under glass, more diseases have made their appearance in the glasshouses than are known in the outdoor crops. Diseases are very erratic in their appearance, and every good grower knows that he must be constantly on the watch and adopt the best methods throughout his work in order to keep them in check.

Many growers have expressed the wish that a bulletin should be available, describing what is known about the tomato diseases which occur in South Australia. An ability to recognise the different diseases and some knowledge of the life history and method of attack of the parasites which cause them is of great value in applying control measures most economically.

Since freedom from disease depends very largely on the employment of good methods in growing the plants, the introductory part of this bulletin deals with general matters which make for healthy growth of tomato plants and the avoidance of disease. The material in this part of the bulletin should be known by every tomato grower.\*

The second and third parts of the article are for reference purposes only, and are so arranged that a grower who has any disease should be able to identify the trouble for himself and to find out as much about the

---

\* The details of construction of glasshouses and seedframes are beyond the scope of the present bulletin. A useful article to consult is that by A. J. Pinn, in the *Agricultural Gazette* of New South Wales, vol. 40, pp. 701-14, "Tomato Culture under Glass."

cause of it as will help him in controlling it. To assist in proper identification, the description of symptoms of each disease has been made as full as possible, and all photographic illustrations have been made from South Australian specimens, which should help to make recognition easy.

No apology is made for giving considerable detail in the discussion of many of the diseases, or for including descriptions and illustrations of the fungi causing them, although these parasites can only be seen under a microscope. The writer has met many tomato growers in the last few years, and has found them eager to know all these details. In fact all that is in this article can be considered as consisting of the answers to questions which have been asked by growers. It is hoped that now the information is compiled in this way it will be of assistance to many more growers and will help them in their efforts to produce tomatoes free from disease. To the many growers who have contributed specimens or assisted in other ways towards the obtaining of the details here set down, the writer extends his thanks.

It will be obvious, after reading this article, that there is still much to be discovered about the best way of controlling some of the most troublesome diseases, especially under the conditions obtaining in South Australian glasshouses. Since steam is not available in these houses, some of the most useful control methods developed in other countries, such as steam sterilisation of the soil, or raising the temperature of the houses above a certain point, are not available here. Whether these can be replaced to some extent by methods of soil treatment, or any other methods, can only be determined by experimental work carried on in the future.

### GROWING HEALTHY PLANTS.

Tomato plants, like all other living organisms, have "likes and dislikes." If they are grown under conditions they like they flourish, and do not seem to be easily susceptible to diseases. If, on the other hand, they are grown under conditions which are not quite right they seem to take diseases more readily. It is, therefore, well worth while taking the trouble to provide the best growing conditions for them, not only in order to avoid diseases, but also that the fruit may be of the best quality, and that there shall be plenty of it. Nothing is so disappointing as to spend months in growing the plants, and then to find that the crop is poor, or the fruit is poor, or that much of it is spoilt by disease.

Undoubtedly one of the main factors influencing good growth and good fruiting is the type of soil, but all the operations which must be gone through, such as choosing the seed, raising the seedlings, transplanting, watering, manuring, &c., also influence the result to some extent. Although this is not primarily a bulletin on general tomato culture it will be valuable from the point of view of avoidance of disease to discuss shortly each of these steps which is concerned in producing general healthy growth. *Nothing is so important in the control of diseases as to prevent them making their appearance if possible, so that disease control is very closely bound up with the best general methods of culture.* It is usually the man who does not grow his crop in the best way who suffers most from disease. It would be a good incentive to using the best methods and controlling diseases to the best advantage if every grower set himself some standard yield to aim at, say 150 half-cases per 100ft. of house.

### THE SOIL.

The type of soil is one of the most important factors influencing the production of good quality fruit. Tomatoes like a deep well-drained soil, preferably of a sandy-loam nature. The best fruit is produced from soils in which the water disappears almost as soon as it is put on, and which are firm to the tread a few hours after they have been soaked. Clayey soils which become puggy after watering are not nearly so good, and if the subsoil is at all close to the surface tomato plants will not grow well on them.

The distribution of tomato glasshouses on the Adelaide Plains illustrates the soil factor very well. Most of the glasshouses are on the banks of the River Torrens, from Paradise to Lockleys, or on the banks of rivers such as the little Para and Sturt. There are patches of good, well-drained soil away from the rivers, but the soil in the average suburban garden round Adelaide does not grow tomatoes to their best. Good fruit can be produced on these soils, however, if adequate attention is given to improving them in the proper direction.

For growing tomatoes commercially, therefore, a prospective grower would pay considerable attention to choosing a good piece of soil on which to start. If it is not well drained, or if the subsoil is less than about 9in. from the surface the land is scarcely worth considering from the standpoint of commercial glasshouse tomato growing. A good piece of advice is to begin by digging a hole, and the deeper it has to be dug before coming to the tighter subsoil layer the better are the tomatoes likely to be.

If for any reason a grower could not secure a piece of the best type of soil, but could obtain, for example, a piece of well-drained soil which was otherwise slightly on the heavy side for tomatoes, it would pay him to spend something on improving it by the incorporation of several loads of sand per glasshouse (and possibly some gypsum if at all clayey) before growing the crop.

Another factor, besides soil type, which should be taken into consideration in choosing a site for tomato glasshouse growing is the equability of the climate and absence of frosts. Generally the closer to the sea the more moderate is the climate, and thus the more favorable for the growth of tomatoes. There are positions along the foothills also where frosts are rare, but as a general rule the soil type is not so favorable in this situation as it is nearer the coast.

One other point should be mentioned while dealing with the influence of soil and climate, and that is that certain varieties of tomato seem to be closely adapted to growing under certain soil and climatic conditions, and do not succeed well when put under other conditions. The "potato-leaved" variety, Burwood Prize, for instance, apparently bears excellent crops in New South Wales, and occasionally in some Hills districts in South Australia, but rarely produces a satisfactory crop on the Adelaide plains. Similarly, the varieties Dwarf Champion, Dwarf Giant, and others do not appear to be suited to Adelaide soil and climate. They are very susceptible to spotted wilt, but even when they escape this disease they do not bear well. There is opportunity for considerable experimental work to discover the tomato varieties best suited to Adelaide conditions, but for the time being there appears to be no tomato so well adapted to these conditions as the widely grown Early Dwarf Red.

## PREPARATION OF THE SOIL.

The way in which the soil is prepared before planting will have a considerable influence on the growth of the plants during the year. After one crop is finished preparation for the next crop should begin as soon as possible. The old plants of the previous year should be cut off about six inches above the ground, the tops dragged outside to dry, and then burnt as soon as possible, and the fallen leaves raked up and burnt also. (Burning is an important aid in reducing the amount of disease about.)

The ground should then be flooded, and next day the roots pulled up by the six-inch pieces of stem left, and these also be taken out, dried, and burnt. If lime is to be added (see below) it is best done at this stage, and the house can then be dug over and left to dry out in the hot weather of February. It seems possible that the high summer temperatures on the Adelaide plains might even have some partial sterilising effect on the soil in the empty glasshouses, for cases frequently occur where a root disease has been bad one year and not the next, although no sterilisation or any other treatment has been given.

When planting time is approaching a very heavy flooding is given to the soil, a heavy dressing of bonedust (about a bag per 100ft. of 15ft. house) and a layer of from 2in. to 4in. of well-rotted stable manure applied, and the whole house dug as deeply as possible. This treatment being given in autumn before the soil is too cold, should help to hold the moisture and warmth as long as possible, so that seedlings put out with only a little superphosphate and a "pot watering" can establish themselves and grow for several weeks before a trench watering becomes necessary. Too early waterings of seedlings after planting out is to be avoided if possible, for it is at the coldest time of the year, and watering would tend to make the ground colder and check growth.

There is a difference of opinion among growers as to the advisability of using stable manure. Some consider that it brings diseases with it, whereas others consider it indispensable. It is probable that its value varies to some extent with the type of soil, but on the whole one would expect it to be beneficial. It should undoubtedly be well rotted, however. It would be best for any grower who is in doubt to use it on one end of a house for several seasons, and he would soon find out for himself whether it was of value on his soil.

The bonedust and stable manure can be considered as the "Base manure" which is put into the soil to form slowly available reserves on which the plants can draw continuously. When fruiting commences dressings of more quickly available and soluble manures such as superphosphate, sulphate of ammonia, and potash are given to supply the elements which are rapidly drained from the soil when heavy crops of fruit are being removed. Under the intense systems of tomato culture in heated houses in Europe the base manure used consists of lime, stable manure, bone meal, bone flour, hoof and horn, and sulphate of potash. It is not necessary to use all these ingredients under South Australian conditions, and most growers do not even use lime. If lime is used it would be preferable to apply it with the first digging, and the stable manure with the later digging. Liming once every two, three, or four years, according to whether the soil is heavier or lighter in texture, would probably be of benefit in most South Australian glasshouses. A fairly heavy dressing, say, from 3cwts. to 5cwts. per 100ft. of 15ft. house, is suggested. Provided that it is applied some two months before the house is planted fresh or quick lime can be used, and may have some beneficial sterilising effect.

## RAISING THE SEEDLINGS.

At present tomato seedlings are raised in all sorts of ways, favorable and unfavorable, and it is only the natural hardiness of the plant which allows many of them to survive the treatment they get in the early stages and still produce a respectable crop. In most cases where a very good crop is seen it is found that good methods were used in the raising of the seedlings.

There are one or two growers who go to the great trouble of raising their seedlings each in a separate small pot. The advantage of this method is that there is no check at planting out time, but almost as good a result with much less labor can be obtained by the tray method. A kerosine case can be cut parallel to the sides into three parts, and if extra wood is available for the centre part three handy trays can be made from each case. Such trays, 21in. by 15in. by 3½in., will hold 63 seedlings planted 2in. apart, and are very convenient for carrying the seedlings about when planting.

Most growers, however, plant directly in the soil in special seedframes situated in a warm position. Some use a part of one of their glasshouses for the raising of their seedlings, and then planting up this house last of all. This method is not to be recommended, however, for the soil does not get a long enough spell from tomatoes, and diseases may multiply and be carried to the other houses with the seedlings. The tray method is probably the best, but is more trouble than planting directly into the soil in seedframes.

Better seedlings would be raised if more attention were given to preparing the soil for the seedbeds a long time ahead. Almost as soon as one year's seedlings are planted out into the houses the preparation for next year's seedlings can begin. Soil and manure can be mixed, and a pit or a heap of the mixture made which is allowed to gradually rot down to a rich loam over a whole year. This provides ideal soil for the raising of strong seedlings the following year.

At sowing time, usually early in March, this soil can be sieved and a little superphosphate turned in with it, and the seed sown in well-levelled beds or trays. In the tray method a little short straw or grass (without seed) is placed over the holes in the bottoms of the boxes, and the trays are then filled with the loam and scraped level with a board, and can be stood in piles until all are ready for sowing.

Seed sowing may be done in two ways. Either the seed is sown very thinly, and seedlings which come up too close thinned out so that all are well spaced, or the seed is first sown moderately thickly in a few trays or in a small part of the bed, and the seedlings which come up later pricked out at the three-leaved stage, as described below. In either case a free-running sample of seed is of great advantage in getting evenness of seedlings, for clumps of seed stuck together make some seedlings crowded and others free. (See page 165, on saving next year's seed.) When evenly sown the seed is covered with a thin layer of the same loamy soil that was used for the trays, sieved through a moderately fine sieve such as can be made from a piece of wire mosquito gauze. A light sprinkling of dry manure over the surface can then be given, but it is not necessary, and it is better to use none at all than too much. Sand is best avoided for covering seeds. The trays are then placed in the seedframe and carefully levelled, and watered with a spray fine enough to prevent any washing of the soil.

The construction of seedframes need not be entered into here, though it may be said that the galvanized rafter is valuable for avoiding the nuisance of drip; and a suitable slope for the lids and a warm, sheltered position facing north will make one less dependent on the manure-bed beneath for a suitable temperature for the growth of the seedlings. Raising the lids

## **TOP BRAND FERTILIZER APPEAL.**

I came from the depths of the earth, from the waters of the sea, from the atmosphere we breathe. My sources are worldwide.

I offer myself as a servant of the Primary Producer, and, in the end, I am free—I pay for myself several times over.

I feed the plants, increase the yield, lower cost of production, make labour more profitable, and release land needed for other purposes.

I make two blades to grow where one grew before, providing feed and food where hunger would prevail. I make possible profit where otherwise loss would accrue. And, while I serve, I leave with the soil a portion of myself which forms a residual asset for years to come.

Plants, like all other forms of life, must feed. It is my function to furnish food for plant life.

I am a service. All I need is an opportunity to show what I can do. Experiment stations throughout the land have given me this opportunity—have tried me out and found my ability not wanting. Farmers everywhere testify to my power.

I am the farmer's friend and mankind's benefactor.

I am **"TOP BRAND SUPER."**

with a brick if the frames get too warm, and lowering them immediately it becomes cool, are also well worth taking the necessary trouble over. The best temperature for the growth of the seedlings is between 60° and 70° F.

When the seed has come up, and the third leaf of the young seedlings is about half an inch long, is the time to prick them out singly at even distances apart in the seedframes or in fresh trays. From 2in. to 3in. apart is the most suitable distance for forming good sturdy seedlings which can be lifted with a square block of soil round their roots when it comes to planting out.

Considerable time can be saved and a much neater result obtained in pricking out if a press board is made studded on the under side at regular intervals (say, every 2in. or 2½in.) with wooden projecting pegs about the size of one's little finger. When the soil in the beds or trays has been prepared the press board is pressed down and, say, 50 to 100 holes for pricking out made all at once. The actual pricking out of the young seedlings should be done by a very careful worker. The young seedlings should be lifted only by their leaves, and not be handled by the stems. They can be quickly separated and dropped into the evenly spaced holes ready for them, and then the pressing and firming done with a suitably shaped wooden dibble. It makes for better seedlings if they are planted deeply—almost as deep as the two seedling leaves.

If a little superphosphate has been placed in the soil, and the seedlings are kept well watered, and the temperature is regulated by proper attention to the raising and lowering of the lids of the frames, the plants quickly establish themselves and become strong and even in appearance. Just about when they begin to touch one another the process of hardening off should begin, the lids being taken right off the frames for part of the time. At first it should be for only a few hours on a sunny day, but the time can soon be lengthened to a whole day, and if there is no danger of frost the lids can be left slightly blocked up all night. After about 10 days of this treatment the seedlings should be very sturdy, and ready for planting out. There should be a good spread of leaves on each seedling, and strong, thick stems, slightly purple in color at the base, paling gradually to green at the top.

If stems or leaves are very purple it indicates that the conditions are too cold (or occasionally that disease is present). If the tray method is being used, cold conditions can be remedied by building a fresh bed of manure under the boxes, but when the seedlings are planted in the soil this method cannot be used. Large growers may later find it advantageous to have some form of controllable artificial heat for the raising of seedlings in seasons when the weather is not the best.

During the whole time of raising the seedlings to this stage they should be inspected periodically, and any diseased ones removed immediately. The main disease which may affect plants at this stage is the Damping-off disease, which attacks the stems just at ground level and causes the young plants to flop over. This will be described in further detail later. It is advisable also to remove at this stage any strangers which may have accidentally got in, and also any obviously weak or backward seedlings. It gives the ones which are left all the better opportunity of developing as strongly as possible, and makes for evenness in the plants for the houses.

#### PLANTING OUT.

When good seedlings have been raised according to the above methods it becomes worth while to give them the best of treatment in planting out. The two important points in planting out are (1) to give the seedlings as

little direct handling as possible and (2) to supply them with the best conditions for commencing active growth immediately.

With regard to (1) the tray method is almost ideal, for the boxes of 60 seedlings can be taken and set along the house, and the seedlings are not disturbed until actually planted. When planting, each seedling can be removed from the box with a sharp trowel with a square of soil surrounding its roots; it is lifted by this square of soil, and the actual seedling need never be touched. Once again, it is better to plant slightly on the deep side. Practically the same methods can be used where the seedlings are grown in the soil of the seed-frames, but the transportation after they have been cut out often tends to shake soil from their roots and they do not get quite such a good start as seedlings which are planted with a lump of the original seedbed soil still undisturbed round their roots.

With regard to (2)—supplying them with the best conditions for commencing active growth immediately—good previous preparation of the soil and the presence of a little superphosphate are the main requisites. The bonedust and manure of the basal dressing is not quite sufficient for best growth, and a little superphosphate should be added when each seedling is planted; it helps the plants to establish themselves as quickly as possible. The plants can also be helped by the choice of a cool, cloudy day for transplanting, and by keeping up the watering fairly close behind the planters.

#### EARLY CARE AND PRUNING.

If the soil has been well prepared the young plants will not need watering for the first month or six weeks, or even two months, after planting out. This helps the plants to quicker growth in the early stages, for the soil is not cooled down by watering at what is practically the coldest time of the year. During this time the wires and strings are adjusted, pruning commenced, and the soil hoed up into the beginnings of the banks. There is no need to bank up too early. Many growers remove a number of the bottom leaves in order to get the banks up quickly, but the plants will probably establish themselves quicker if the bottom leaves are left on as long as possible.

The operation of pruning gives another valuable opportunity for passing every plant in review and removing any which are diseased or even not up standard. It is in these early stages that the foundations for the future even and healthy growth of the whole house are laid. The man who thinks when he comes to a poor plant, "Oh, I'll leave that in and see if I can doctor it up a bit," is the man who will never get a house full of good, even, healthy plants, and who may get instead disease gradually spreading and appearing here and there all over his houses. The secret of success is, "Out with the backward plant as soon as possible, and fill its place with a sturdy plant," preferably one from a stock of replants at the end of a special house, planted out at the same time as the main batch. In every population of thousands there must occur some poor specimens, and so a supply of good replants should be provided as a matter of course.

This removal of diseased and backward plants can be done in a good way and a bad way, however. The bad way is to do it while the pruning is going on, and then go on pruning the next healthy plant. There is danger in that method. The good way is not to touch the backward plant, but to put a light stake in beside it, and then come along at the end of the day and remove carefully all the marked plants with the soil around their roots, and cart them away and bury them. A pit for burying diseased plants, or an incinerator, should be just as necessary an item as a roof to the glass-

house, and yet on how few properties is it found? After burying or burning all the poor plants the hands should be washed with soap, and healthy replants planted immediately into the gaps with a little superphosphate, and watered in with Cheshunt mixture. This routine of pulling out and replanting only at the end of the day's work is not complicated, and really saves time in the end. It is one of the best safeguards against spreading diseases.

Good growers will make this careful "inspection" a routine, which is carried out at least twice a week. The sooner a diseased plant is out the better. When the eye becomes practised diseased plants are very quickly seen, especially in the morning. A thousand plants can be inspected by slowly walking up one side of a glasshouse and down the other in less than five minutes. This means that a grower with 10,000 plants could inspect them all in about an hour. He can carry a small bundle of stakes with him and mark those to be removed, and the removal and replanting should be left till the end of the day as described above. The reward will be houses of even growth and every plant bearing its quota of fruit.

The best way of pruning is pulling the young side-shoots out with the finger and thumb as soon as they are about  $\frac{1}{2}$  in. long and big enough to catch hold of. If other work has delayed pruning, it may be advisable to carry a pruning knife for the bigger shoots. In all cases it would be a wise plan to wash the hands and the knife with soap and water after finishing each house. Remember not to touch a backward plant as soon as it is come to, but stick a light stake in beside it. If virus diseases are present in the house it may be advisable not to prune more frequently than once a fortnight, as explained in the section on Mosaic Disease.

When the plants are above the top wire they are "topped" just above a strong side shoot, and the temporary check which is given assists in swelling the third and fourth trusses of fruit.

Finally, a word should be said about watering and hoeing. Good growth of the plants depends very largely on good growth of the roots. Good growth of the roots depends on air in the soil as well as water. That is why plants on open-textured soils grow better than those on tight soils. Proper watering must be regulated according to the texture of the soil, and is an art which can only be acquired by practice. After every watering the surface should be cultivated either with the pronged hoe or with a weighted hand tyne cultivator. The latter is an excellent tool for free-working soils and saves a great amount of time. Hoeing or cultivating pays for itself by promoting vigorous growth. Lastly, weeds should be kept down round the glasshouses. Have everything outside as clean and neat as inside and another link will be added in the chain of methods of disease control.

#### MANURING.

The "base manure," which is worked into the soil at the time of preparation of the house for planting, has already been described on page 157. This, with the little superphosphate given to each seedling at planting time, is sufficient to carry the plants on until the first truss of fruit is swelling.

From that time onwards manures are supplied with the object of "swelling the fruit." This really means just supplying the soil with the right amount of plant food to enable the fruit to develop to its maximum. The fruit which is harvested is continually draining from the soil its

supply of phosphate, nitrogen, and potash, and if fresh supplies of these three chemical substances are not added the fruit on the upper trusses cannot develop to the full extent.

Phosphate is best supplied as 45 per cent. water-soluble superphosphate; nitrogen is best supplied as sulphate of ammonia, which is a quickly available form, together with blood, which is more slowly available; potash is best supplied as sulphate of potash. The following proportions give a mixture which has been found very satisfactory:—

- 2 parts superphosphate 45 per cent.
- 1 part sulphate of ammonia.
- 1 part blood manure (or M.A.B.).
- 1 part sulphate of potash.

The same manure can be used without the blood if desired.

The ingredients should be measured out with a tin or by the shovelful and placed together in a heap on a cement floor and turned over with the shovel until thoroughly mixed. The mixture is then used at the rate of about 50lbs. per 100ft. of house just before waterings. About four or five applications during the season are usually sufficient. It is best if the manure is scratched into the soil along the trenches with a pronged hoe before watering, so that it is not all carried along with the stream of water. This is where the man who has chosen the best soil reaps some advantage, for clayey soils set hard when watering becomes frequent, and the hoeing in of manure becomes quite a work.

The time of application of each lot of manure, which falls roughly at periods between a fortnight and three weeks, should be regulated to some extent according to the pickings of the fruit. If the precautions detailed on page 161 on removal of backward plants have been consistently observed from the start, the plants in the houses should be very even, and picking of the successive trusses should occur very regularly. Under these conditions it is best if each fresh application of manure is given about the time the picking from one truss is coming to an end and the fruit on the truss next above is commencing to swell.

A word may be said here about the value of potash for tomatoes. South Australian soils are fairly well supplied with potash, and most plants do not need any more than is normally available in the soil. But the tomato requires a lot of potash, and responds well to extra dressings, not so much in size or amount of fruit as in quality and firmness. Dressings of nitrogenous manures such as sulphate of ammonia swell the fruit well, but if potash is not supplied in addition the fruit is apt to become too soft and watery. Research work in England has shown that the potash requirement of tomato plants varies with the amount of sunshine received, less potash being required during bright sunny weather than under dull conditions. The function of potash may therefore be considered to be the giving of the necessary "firmness" to plants which in other respects are being forced, and which would become too soft and sappy without it. Potash is also of value in minimising losses from streak disease, if this is present.

The question is frequently asked, "Is it better to use nitrate of soda or sulphate of ammonia as a nitrogenous manure?" The question involves problems in soil chemistry as well as in plant growth. Both materials are good sources of nitrogen, but it may be stated here that the experience of growers in England is in favor of sulphate of ammonia in preference to nitrate of soda for tomato growing.

## OTHER FACTORS AFFECTING FRUIT PRODUCTION.

*Excessive Cold.*—In the unheated type of glasshouse in common use in South Australia it is not at all uncommon for at least one truss of fruit to be lost as a result of a frost coming just at the time pollination should be taking place. It is always one of the lower trusses which is lost in this way, and therefore the highest priced fruit. At present nothing seems to be done to check the trouble. It is very probable that in the future, frost-alarm thermometers may be fitted in the glasshouses which will call the grower from his bed if the temperature drops below a certain point, and some smoke or other device used to check the harmful effect of the cold.

*Pollination.*—No special attention is given to pollination by the majority of growers in South Australia, but in some countries elaborate pains are taken to ensure good pollination. The more laborious of these, such as going along with a watch-glass of pollen and dipping the stigma of every flower into it, are not worth consideration for South Australian conditions, where pollination seems to occur so well by itself. The method adopted in Canada, however, where glasshouse growers go along with a rabbit's foot tied to the end of a long stick and just lightly touch the open flowers might be found to be of benefit under our conditions, especially in helping the setting of the early trusses. Another method is to go along and tap the wires every day to give the plants a little shake and aid pollination in this way, but this would not be so effective as the rabbit's foot.

It is not generally realised that the more thorough the pollination the better the development of the fruit, and that the explanation of a lot of the small fruit at times when ample manure seems to have been provided is probably defective pollination. If there were no pollination no fruit would develop at all.

*Excessive Heat.*—Just as the glasshouses get too cold in winter they also get too hot in summer. The usual type of glasshouse round Adelaide is not provided with any means of controlling the ventilation other than by opening the doors at the ends and removing panes along the sides. It is probable that better control of ventilation, especially ridge-pole ventilation, will soon be incorporated in any new glasshouses which are built. The optimum temperature for the growth of the tomato plant in the younger stages has been worked out in England to about 65° F., and while the plants probably need somewhat higher temperatures by the time they come to fruiting it is probable that temperatures over 80° are above the optimum. In the not far distant future every good grower will have a thermometer in his houses, and regulate the ventilation according to the reading of the thermometer.

As the houses are constructed at present, a light spraying of whitewash over the roof, put on some time in December, should help to keep the temperature down and prevent sunburn. A wash containing lime should not be used, however, because it gradually etches the glass. Plain flour, with a very little boiled flour paste added as a sticker, would be the best spray, and it should be washed off as soon as the season is over.

*Diseases.*—Another factor influencing fruit production is the presence of diseases. These are dealt with in detail later, but one or two of the less obvious ones may be mentioned here:—

*Eel-worm*, which causes clubby roots, often does not show any very definite symptoms on the tops of the plants, and the first sign of its presence may be only a failure of the fruit to set, or, at other times, a general falling-off in vigor and in the swelling of the fruit. If these symptoms are noticed, a plant should be pulled up and its roots examined, when the presence of irregular swellings on the roots will immediately betray the presence of eel-worms.

*Mosaic* disease, which causes a faint mottling and curling of the leaves, often reduces fruit production also. It will be more fully discussed later.

*Root* diseases are often rather difficult to detect in the early stages, but the practised eye can note at a glance the slightly thin looking top, the tendency for the lower leaves to yellow slightly, and other signs. These will be dealt with in a subsequent issue.

#### SAVING NEXT YEAR'S SEED.

One of the biggest causes of the spread of disease is probably the buying of seedlings. Any grower in a big enough way to need a thousand or more seedlings should never think of buying them, but raise them himself according to the methods outlined above. Seed rarely carries any disease, whereas seedlings frequently do so.

Not only should the seedlings be raised by the grower, but also the seed itself should be saved by the grower. If he follows good methods he will be certain that he has good seedlings and of a good type. There is no truth in the idea that a periodical change of seed is necessary; in fact, the reverse is the case. By careful selection of his seed plants a grower can build up a better and more uniform type of plant than he started with, and gradually improve it from year to year. Whereas if he goes and buys a big batch of fresh seed, of which he does not know the history, he may get non-uniform plants again, from which he will have to begin the process of selection over again.

## LACK OF ARSENIC TO BLAME!

### ON THE QUESTION OF INEFFICIENT SHEEP DIPS—

Many dips on the market contain a low percentage of arsenic, yet they are called **ARSENICAL DIPS**, but are inefficient.

## YOUNG'S SHEEP DIP

(POWDER)

complies with the requirements of the Stock and Brands Department for South Australia, and contains considerably more than the percentage of Arsenic stipulated under the Act, and will **KILL TICK and LICE**, and resist the Blowfly attack.

Try also **YOUNG'S BRACKISH WATER SHEEP DIP**. Mixes readily with Fresh or Brackish Water.

FROM ALL STORES.

Sole Agents.

CURRIE ST., ADELAIDE.

In saving one's own seed the most important part of the process is the choosing of the seed plants. This should be done by choosing plants which show a combination of as many desirable characters as possible. Not only size of fruit, but shape, earliness, and other characters, type of fruit-truss, number of trusses, and evenness of distribution up the stem should all be taken into account. For this purpose it is necessary to do the choosing of the seed plants just before the first fruit is picked, otherwise some of the evidence has already gone. Also, the aim should be to save the whole of the seed from the chosen plants—not to sell the fruit of lower trusses and keep only the later fruit for seed; this would be false economy.

To secure the most even type of fruit, a single plant—the best that can be found—should be chosen, and the seed from this kept separate and planted in a block in one of the best houses. The seedplants for the bulk of the following season could then all be chosen from this block, while again the very best plant is selected for separate seed-saving as before. This practice of saving seed from single plants makes for uniformity of plants and maintenance of the best and most even type.

Since the fruit picker goes along the rows with his back bent and his eyes only on the bottom trusses of fruit, it is no good ticketing seedplants on the top wire. Their fruit would be picked with all the rest and go to market "as sure as eggs." The best way to mark the chosen seedplants is to have a long strip of white calico and tie it on the top wire and wind it down round the plant so that it passes every fruit truss and acts as a warning—not to pick!

Let the fruit get thoroughly ripe on the plant, and then bring it in for extracting the seed. This is best done by cutting the fruit in half and scraping out the seeds in their pulp into a tin and adding about an equal quantity of water. Let stand for a few days, when a light white scum due to fermentation will be seen to form on the top of the liquid. Stir occasionally and pour off the top liquid once or twice. The best seed sinks to the bottom and becomes bright and clean. There is no danger in its being under water for a week. The fermentation has dissolved away the mucilaginous coating round the seeds, and they can now be washed clean by several rinsings or by pouring into a gravy strainer and running a stream of water through the strainer for a while. The seed is then spread out on canvas (blotting paper or newspaper will do) and allowed to dry. When cleaned by this method the seeds do not stick into clumps as they do when extracted straight from the fruit. The free single seeds are much better for sowing, and form better young seedlings for pricking out.

Seed obtained from the best healthy plants in this way does not need disinfection before planting. It grows better without treatment. If new seed is bought, however (perhaps to obtain a new variety), from some source where the seedplants have not been seen, it is advisable to disinfect it. Several cases have come under notice in which diseases have appeared in houses following the introduction of some outside seed. The best way to disinfect seed is to buy some 1:1000 corrosive sublimate solution (mercuric chloride) at the chemist; then soak the seed in this solution for 10 minutes, wash several times in water, and spread out to dry. Remember that corrosive sublimate is very poisonous.

*(To be continued.)*

## DRESSMAKING AND FANCY STITCHERY.

[By Miss ELLIE CAMPBELL, Inspector of Domestic Arts, Education Department.]

Spring is here, so thoughts turn to frocks and clothing. The wardrobes are turned out, and the contents looked over for renovations or replacements. In the planning and scheme of work, perhaps the following hints might be of some help to the woman who is distant from the costumiere or dressmaker, and has to depend on her own efforts. Unfortunately, all phases of home dressmaking could not be dealt with in one article, for it would become a volume, so just a few important points are selected.

Nowadays the designers and the commercial pattern companies have done much to assist in simplifying dressmaking for the housewife; thus with a little care and effort the clothing account can be considerably reduced. Several firms prepare and publish patterns for styles illustrated in their fashion books. There are two ways of procuring a commercial pattern; the most common way is to carefully look through a fashion book, and select the style of frock that is most becoming, then the pattern is ordered according to the bust measurement for a blouse, jumper, or frock, or to the hip measurement for a skirt. These patterns are drafted in proportion to the measurements of an average figure. The second way to procure a pattern is to send the measurements of the person to the firm, and indicate the style of garment that is required; they then draft the pattern—this is a surer way of obtaining a good fit.

A garment must fit the body well for the person to feel comfortable and at ease in it. If it fits well it will grace the line of the body, and will have a distinctive look. To send the measurements to the designers, it is well to know just where and how to take the measures, also they are very handy in order to check the size of a "commercial" pattern. The person should stand naturally, and the arms should not be raised nor the head lowered whilst the measures are being taken. The diagrams following will show where to take the various measures.

The neck measure should be taken comfortably, not too loosely nor too firmly.

The shoulder measurement is taken from where the neck joins the shoulder to the top of the arm joint.

The cross chest should be taken firmly across the chest, above the bust line, just where the arms join the body. The bust measurement is taken right around the body under the arms, passing over the shoulderblades and across the fullest part of the bust. It should be a loose measurement, to allow for expansion of the chest and for free movement. The waist measurement should be firmly taken around the body a little below the ribs. This is not always the waist line of the frocks—that is obtained when designing the gown.

FRONT.

BACK.

The underarm is taken down the side from the armpit to the waist line.

The cross back is taken above the bust measurement, where the arms join the body.

The hip measurement is taken loosely, 7in. below the waist. This measurement has to allow for the spring of the legs and body.

The down front measurement is taken from the point where the neck joins the shoulder, over the bust, down centre front to the ground. The height of the edge of hem above the ground is to be deducted to give the correct down front length of frock. The down back is taken from the bone at the nape of neck to the ground, and the height of hem above ground deducted as for front measurement.

The sleeve measurement is taken with the arm bent, the hand resting on the chest. Measure from top of shoulder joint, around point of elbow to the wrist bone. This allows for the bend of the arm.

Wrist, measure around the broadest part of the hand, keeping the thumb in the palm of hand.

It is most important that these measurements be taken very accurately, as the whole fit of garment will depend on them, also the amount of material to be used will be governed by the pattern. With these measurements the commercial patterns can be tested and adjusted.

In order that the pattern may be pieced together properly, various methods have been devised to indicate the pieces to be joined; it is necessary to understand and read the patterns. One method is the use of lines, arrows, and wording. The broad dark line is the cutting line; the fine broken line is the seam line; the double arrow indicates the way of the grain of the material—that is the way of the threads, not the pattern of the material; thus it can be a crossway grain or a lengthwise grain, the way of the selvedge, the darkened notches are numbered and they correspond. Another method is the use of perforations. Large punctures in pairs, in a line, are used to indicate the way of the grain, smaller punctures marking the seam line; yet smaller punctures to indicate tucks, gathers, or pleats. The edge of the paper pattern is the cutting line. Folds are indicated by three punctures forming a triangle. It is most essential that the pattern should be placed on the grain of material correctly, as this affects the hang of the garment.

Having read and tested the pattern, some slight alteration might be necessary to give good fit. Following are a few suggestions for keeping the line and design, although altering the measurements:—

1. To lengthen pattern 3ins. or 4ins.—Cut across the front pattern 2ins. above waistline, and spread pattern 1½ins. or 2ins. Cut across the front pattern below hip-line and let in the necessary 1½ins. or 2ins. This will give the extra length.

Cut the back pattern to correspond.

**LUCERNE AND CLOVERS ALWAYS AVAILABLE.**

**EXPERT ADVICE ON GRASSES AND CLOVERS.**

2. To shorten pattern 4ins., place an inch tuck across the pattern between the waist and bust lines, also another inch tuck below the hipline.

3. To widen a pattern that is tight at the hips, cut pattern from a point 2ins. in from corner of armhole down to hemline, and spread the necessary amount; fasten to new paper. This will give extra width for hips and spring of legs when walking.

4. To alter pattern to suit a round back and flat chest—Cut pattern along line of cross back measurement and spread it the necessary amount. Put a tuck in the front on cross chestline, taking up the same amount as was let into back. Add same amount to lower edge of front to adjust the hemline.
5. To shorten a pattern with a circular skirt—Place small tuck in bodice, between waist and bust lines. Cut skirt pattern in more than one place, being careful to have even distance top and hem. Spread to allow the new hemline to have same measurement, and cut off extra length, being sure to keep the circular cut.
6. To make a circular yoke pattern larger at the hips—Cut the pattern in three places, from the waistline to the hipline, and spread the necessary amount.  
To shorten the waistline of circular yoke—Place three tucks in yoke, at equal distances, taking up the extra length between them; taper the tucks from waist to hipline.
7. To adjust length of skirt pattern, that has two or more pieces—Make tucks, or let in extra length, 6ins. below hipline.

8. To lengthen or shorten sleeve pattern, make the adjustments above and below the elbowline, by either letting in the extra length, or taking up the extra amount in tucks.
9. To make a fuller sleeve, cut from top of curve to middle of cuff, and spread pattern to arm measurement, adjust curve by equal amount that is taken up in pleats in pattern. Adjust armholes equal amount.
10. To make deeper armhole, an equal amount must be cut from back and front of bodice pattern, also both sides of sleeve curve. Be careful to deepen both sides.

When the pattern is adjusted to the required measurements, it is advisable to place the whole pattern on the material, before starting to cut out. Often an appreciable amount of material can be saved with careful placing; take time to think it out, then thoroughly look over the placement. Do not be in too great a hurry to cut, as a wrong cut often wastes material. To prove the pattern, before cutting out in expensive cloth, make the garment up for a housefrock in a cheap material, such as zephyr or cambric. This will often give confidence and assurance that the better garment will give satisfaction.

Careful and neat finishings are advisable, as the seams and hems are strengthened. There are two kinds of seams: the French or double seam, and a flat seam. In this seam it is necessary to neaten the edges of the material to prevent fraying; this can be done by either overcasting the edge, and keeping it flat, turning the raw edge in and machining down, or by nicking along the edge of material (this is known as pinking the edge).

The neck, and sometimes the hem, can be bound by a bias bind—here the bind must be on the true cross, or bias, for it to sit correctly. Necks and cuffs can be faced and piped; the facing should be cut similar to the part to be faced. Hems can be slip-stitched, or if light material, hemstitched. Buttonholes can be worked or bound, and they should be carefully finished off.

The finishing leads to longer wear and service of the garment. The appearance of the garment, especially in children's clothes, is often improved by a little simple stitchery around the collar, cuffs, and hem.

A few well known and selected stitches that can be used for this purpose are here illustrated and explained:—

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

### PINNAROO LINE FARMERS' CONFERENCE.

The Seventeenth Annual Conference of Branches of the Agricultural Bureau on the Pinnaroo Line was held at Lameroo, on Thursday, August 1st. The Department of Agriculture was represented by Messrs. F. Coleman (Chairman), P. H. Jones, (Member, Advisory Board of Agriculture), Professor A. J. Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director of Agriculture), R. L. Griffiths (District Agricultural Instructor), A. H. Robin, B.V.Sc. (Government Veterinary Officer), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary). Delegates were present from the Pinnaroo, Parilla Well, Parilla, Clanfield, Geranium, Parrakee, and Marama Branches of the Agricultural Bureau. Mr. J. L. Koch (Chairman of the Lameroo Branch) occupied the chair, and extended a cordial welcome to officers of the Department and delegates from neighboring Branches. Mr. F. Coleman delivered the opening address. The following papers were read and discussed:—"Conservation of Fodder," Mr. A. Young (Pinnaroo); "Rural Organisation," Mr. L. Orwell (Clanfield); "Marketing Wheat by Grades," Mr. H. Davis (Pinnaroo); "Stabilising Primary Products," Mr. R. McKenzie (Pinnaroo); "Wheats for the Mallee Lands," Mr. A. Fischer (Pinnaroo); "Economy on the Farm," Mr. H. Johnson (Parilla); "Grow More Wheat," Mr. R. Jacob (Geranium).

Mr. F. Coleman presented the following trophies, won in the 1929 Chandos Crop Competition:—First Prize—Mr. W. N. Cross (Geranium), 93 points, silver cup; Second Prize—Mr. A. Beelitz (Parrakee), 92½ points, set of stainless knives; Third Prize—Mr. W. E. Beelitz (Jabuk), pair of electroplated vases; Fourth Prize—Mr. E. Williams (Jabuk). A handsome silver cup was presented to Mr. M. R. Fraser, of Jabuk, who secured the highest aggregate of points in the competition over the seasons 1927, 1928, and 1929. For a Junior Competition, a trophy consisting of a writing desk was donated by Mr. F. R. Koch, of Wilkawatt, for farmers' sons under 17 and not over 21 years of age. The competition was won by Mr. V. Polkinghorne, of Geranium. Mr. Koch was the recipient of many sincere congratulations for the interest that he had shown in donating a prize for competition amongst the young men of the Pinnaroo Line District.

During the session devoted to Free Parliament many questions were answered by Departmental officers, and the following resolutions were carried:—(a) "That the reduced freights in operation at the present time for the carriage of super be extended until the 1st of June." (b) "That the Government be asked to introduce a scheme to provide subsidies for the purchase of draught stallions." (c) "That the 1931 Conference should be held at Pinnaroo." (d) "That all Agricultural Instructors be eligible to judge agricultural exhibits at shows if required." (e) "That in view of the high cost of production and low prices prevailing for wheat this Conference strongly recommends to the wheat merchants and wheat pool that the agents' receiving fee be reduced by ½d. per bushel." (f) "That before any further expense is incurred to make provision of carriage of heavy freight on the Tailm Bend-Adelaide railway line, a full investigation as to the possibility of a southern or Murray port be made." (g) "That this Conference resolves that it be made possible to obtain a transfer from one Branch to another instead of having to be re-nominated."

A special session was held for women. Mrs. Koch presided, and delegates were present from the Pinnaroo, Parilla, Parilla Well, and Wilkawatt Branches. The following papers were read and discussed:—"Butter Making," Mrs. C. Phillis (Parilla); "Domestic Art in the Home," Mrs. H. Fewings (Pinnaroo); "Utilisation of Cold Meat," Mrs. C. Mattiske (Pinnaroo).

### CONFERENCE AT MURRAY BRIDGE.

The Annual Conference of Branches of the Agricultural Bureau situated in the Southern Districts of the State was held at Murray Bridge on August 20th. Mr. G. Jeffrey (Member Advisory Board of Agriculture), Prof. A. J. Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), P. H. Suter (Dairy Instructor), C. T. McKenna, B.V.Sc. (Government Veterinary Officer), R. Hill, and E. Leishman (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary, Agricultural Bureau) represented the Department of Agriculture. There was an excellent attendance of delegates from the following Branches:—Monarto South, Hartley, Rapid Bay, Murray Bridge, Strathalbyn, Milang, Brinkley, Bowhill, Rockwood, Coomandook, Blackheath, Langhorne's Creek, Port Elliot, and Shoal Bay. Mr. Wells, President of the local Branch, presided over the Conference. The President's remarks were supported by Mr. Homberg (Mayor of Murray Bridge), who extended a civic welcome to the visitors. The opening address was delivered by Mr. G. Jeffrey (Member Advisory Board of Agriculture).

The following papers were read and discussed:—"Increasing Farm Production," Mr. E. W. Pearson (Brinkley); "Experimental Farms and Their Value," Mr. L. Rust (Brinkley); "Fencing," Mr. R. Borrett (Langhorne's Creek); "Dairying in South Australia in Relation to the World's Markets," Mr. E. Fromen (Manager Dairy Department South Australian Farmers' Union); "Summer Dairying," Mr. J. M. Hudd (Bletchley); "Finance and Farm Bookkeeping," Mr. H. Kuchel (Murray Bridge); "Dairying in conjunction with Mixed Farming," Mr. A. White (Port Elliot).

During "Free Parliament" the following resolutions were carried:—

Invitations were received from Kangaroo Island, Strathalbyn, and Langhorne's Creek as centres for the 1931 Conference. It was decided to hold the next gathering at Langhorne's Creek. It was also decided that the Advisory Board endeavor to arrange for a Conference on Kangaroo Island towards the end of March, 1931. "That this Conference strongly recommends that the present Government maintain the present agricultural institutions and officers and staff connected with the rural industry, which we consider is essential in the interests of the community and State in general, and we strongly urge the Advisory Board to bring this before the Government at the earliest opportunity." "That immediate steps be taken to call a Dairymen's Conference, where all phases of the industry can be discussed, and that the Conference be held in Adelaide." "That the Dairy Cattle Improvement Act, 1921, be amended by substituting the words 'nine months' in place of 'six months' when referring to the licensing of bulls." "That

the wild or bitter melon be placed on the Noxious Weeds Act." "That the destruction of African boxthorn be compulsory." "That discussions on subjects of economical importance to the man on the land, even though of political flavor, be allowed at Bureau meetings."

Departmental officers replied to numerous questions, and Conference concluded with an address, "Dairying in the Murray Valley," by Mr. H. B. Barlow (Chief Dairy Instructor).

### HILLS PRODUCERS IN CONFERENCE.

An excellent representation of delegates of Branches of the Agricultural Bureau met in Conference at Balhannah on August 28th. Delegates to the number of over 100 were present from the following Branches:—Ironbank, Uraidla, Clarendon, Lenswood, Blackwood, Balhannah, Gumeracha, Mount Pleasant, Tweedvale, Cherry Gardens, Longwood, and Scott's Bottom.

The Department of Agriculture were represented by Messrs. H. N. Wicks, H. S. Taylor, P. H. Jones, J. W. Sandford (members Advisory Board of Agriculture), Professor A. J. Perkins (Director of Agriculture), W. J. Spafford (Deputy Director of Agriculture), Geo. Quinn (Chief Horticultural Instructor), H. B. Barlow (Chief Dairy Instructor), District Instructors, and the General Secretary (Mr. H. C. Pritchard).

The Conference was presided over by Mr. E. Mattner, of the Balhannah Branch. Mr. H. N. Wicks (Vice-Chairman of the Advisory Board of Agriculture) delivered the opening address.

Keen discussions arose from the reading of the following papers:—"Manures and Fruit Growing," Mr. A. Peacock (Balhannah); "Dairying," Mr. E. Mattner (Balhannah); "Marketing Amendments," Mr. W. Bishop (Lenswood); "The Carol Bean," Mr. V. Tapscott (Mount Pleasant).

During "Free Parliament" the following resolutions were carried:—

(a) "That there be no open season for opossums and that landholders be the only persons allowed to take opossums on their own property." (b) "That this Conference requests that, considering the damage done by the fox, the month of March be set aside for the simultaneous destruction of foxes, and that it be an offence to liberate any fox." (c) "It was decided that the 1931 Conference be held at Mount Pleasant." (d) "That the Waite Agricultural Research Institute be requested to initiate research work into the development of the fruit buds in the apple, with a view to determining as to what period the wood bud changes into the fruit bud." (e) "That Branches of the Agricultural Bureau form Advisory Committees to advise new settlers coming into the district of the capabilities of land which they intend to take up." (f) "This meeting desires to place on record its appreciation of the good work carried on in the Blackwood Experimental Orchard and trusts that the Government finds sufficient funds to ensure continuity of this work." (g) "That this Conference heartily supports the action taken by the Fruitgrowers' and Market Gardeners' Association in their efforts to bring about a better position from the fruitgrowing point of view in the sugar industry." (h) "That this Conference emphatically disapproves of the present agreement between the Commonwealth Government and the Queensland sugar interests, and strongly urges that the agreement be not renewed." (i) "That the Advisory Board of Agriculture be requested to bring the foregoing resolution under the notice of the Sugar Inquiry Committee appointed by the Prime Minister." (j) "That steps be taken to investigate the possibility of controlling fruit crops by systematic manuring."

The evening session was occupied with an address, illustrated with lantern slides, "Principles of Pasture Improvement," by Mr. H. Trumble, M. Agric. Sc., Waite Research Institute).

## ADVISORY BOARD OF AGRICULTURE.

---

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, August 27th, there being present Messrs. F. Coleman (Chairman), H. N. Wicks (Vice Chairman), J. W. Sandford, R. H. Martin, H. S. Taylor, P. H. Jones, A. L. McEwin, S. Shepherd, G. Jeffrey, Prof. A. J. Perkins (Director of Agriculture), Dr. A. E. V. Richardson (Director, Waite Research Institute), Messrs. W. R. Birks (Principal, Roseworthy Agricultural College), and H. C. Pritchard (Secretary). An apology was received from Mr. A. J. Cooke.

*Root Gall in Fruit Trees.*—Mr. Geo. Quinn (Chief Horticultural Instructor) submitted the following report on a resolution of last year's Conference of Hills Branches that the Department of Agriculture take immediate steps to ascertain the cause and remedy of root gall in fruit trees, &c.:—"I have to report that this matter was taken up some years ago by the Horticultural Branch in conjunction with Professor Osborn, Professor of Botany and Parasitology of the University of Adelaide. Samples of the galls were supplied to him from time to time in all stages of growth, and he endeavored to determine if the cause was an organism, as had been claimed in the United States of America for a similar defect. I understand Professor Osborn isolated a bacterial organism from the fresh tissues of a gall which he thought would be found to be identical with the *Pseudomonas tumefaciens* described by Erwin Smith and Townsend and other American Plant Pathologists. The removal soon afterwards of Professor Osborn to the University of Sydney precluded further bacteriological study on the subject. With a view to endeavoring to ascertain the possibilities of the dissemination of the gall by ordinary orchard practices, such as pruning the plants and tilling the soil, I secured specimens of young apple trees from local sources, and from nursery stock ex-Victorian nurseries affected by fresh growing galls on their roots. Two dozen young trees of apple, almond, and loquat were secured, all of which were apparently free from the gall. The bark on the stems of half of these trees was sliced and raised to expose the sap layers just below ground level, and the scraped juice and thin slices of tissue of the freshly cut galls introduced beneath it, prior to tying the bark back into close contact with the cambium. The other half of the trees, which were used as checks, were similarly sliced with a sterilised knife only, and tied back in a like manner. Both lots were planted side by side in the vinery at the Adelaide Experimental Orchard. Along with the above, two apple trees, on the roots of which fresh galls were growing, were planted side by side with two clean rooted apple trees, and afterwards the sliced surfaces of fresh galls were tied and bound under the overlapping bark of their stems, below ground level. Thirteen months later all of the trees were very carefully dug up and the soil hosed off the roots. In no instance had the slicing caused infection to be transmitted to the clean trees, and the intergrafted gall had dried and crumbled to powder under pressure, though still adhering to the roots of their respective original host trees. The American investigators have transmitted through pure cultures their crown or root gall organism from various fruit trees to others, as well as to many common garden plants, and produced the galls on them both above and below the ground. In California it is claimed quite 70 per cent. of the soils are infected by this or similar forms of Bacteria, and trees planted therein are infected suspectedly through wounds made into the sap bearing tissues. The incidence of the gall found here commences in a small wart-like growth on the roots, such as is

caused by eelworms or Bacteria, in the case of the roots of legumes. It rapidly enlarges and grows throughout the vegetative season of the host plant, and then the outer and greater bulk dries up into hardened semi-woody mass, in which the tissues are twisted and superimposed into a multitude of irregular, over-lapping, short folds. It is evident the tree building material concentrated to the injured spot has been prevented from forming normally co-ordinated groups of cells capable of maintaining life. Although the galls may assume such large dimensions, a close examination usually reveals the fact that the connecting tissue between the host and a large gall may not be thicker than the cross section of a pencil, or approximately  $\frac{1}{4}$  in. My observations lead me to conclude that the defect is much more abundant on trees planted on sandy soils in warm districts. Among the stone fruits, the almond, peach, and plum are more attacked than the apricot; the pear appears particularly susceptible to gall injuries, and the apple not nearly so, in fact, it has not come under my notice on mature apple trees. Citrus trees, if attacked at all, are never reported as seriously injured. The location on the tree of the gall is of the utmost importance. If attached to the collar or crown where the stem and roots meet, there is great danger of the tree being totally ruined. If the galls are attached to roots a foot or more away from the stem, trees may be infected for many years without displaying any particular disability in consequence. I have dug up several galls ranging from the size of a clenched fist to as large as a child's head attached to roots not thicker than a human finger, and yet the fifteen year old peach tree host gave no sign of inconvenience therefrom and continued to progress for years afterwards, though other galls were subsequently unearthed. As far as remedial measures have been applied, it is indicated that planters should examine young nursery stock for the presence of galls on the roots or crowns, and carefully cut away any found there before planting the trees. As seldom any evidence is found on the young trees at planting time, they should be watched during the first few years for the appearance of any gall-like callosities showing on the stem above the root crown. If any are seen, they should be carefully cut away into the healthy sap layers below, using a sharp chisel or knife, and an antiseptic dressing such as Bordeaux paint (consisting of 1½ lbs. of copper sulphate and 3 lbs. of lime in 2 galls. of water) should be applied to the wounded surface, before painting it over with lead paint, tar, or asphaltum, to ward off moisture. In California, some growers claim if the trees are carried safely over the first five or six years they are usually safe from gall attacks afterwards. In respect to replanting over the positions where gall diseased trees have been removed, our experience at the Experimental Orchard at Berri may be worth citing. There, a number of pear trees developed huge crown galls below the surface, and when the stunting effect on the tops began to indicate something amiss, excavation revealed the cause. Several of these trees were dug out during the summer and the ground excavated for replanting the following winter. When the soil was filled in again the galls, which were also found on the roots, were pulverised and mixed with the soil into which, other apparently clean young pear trees were planted. About four years later these young trees, which were still growing nicely, were dug up, and it was found that some of their roots carried galls varying from about the size of a grape berry to that of a fowl's egg. Whether, in this instance, the remains of the old galls or the soil itself was the cause of this infection I am unable to say, but the fact remains as stated. At any rate, no harm would be done by collecting and burning over the spot all of the excavated roots and galls, together with any other trash calculated to sterilise the soil about to be replaced when re-planting."

*Resolutions from Conferences, Pinnaroo Line Branches.*—(a) "That this Conference resolves that it be made possible to obtain a transfer from one Branch to another instead of having to be re-nominated." Branches of the Bureau are informed that a transfer from one Branch to another will be effected on application being made to the General Secretary. (b) "That in view of the high cost of production and low prices

prevailing for wheat, this Conference strongly recommends to the wheat merchants and wheat pool that the agents' receiving fee be reduced by  $\frac{1}{4}$ d. per bushel." It was decided to bring the resolution under the notice of the Corn Trade Section of the Chamber of Commerce, and the Wheat Pool. (c) "That the Government be asked to introduce a scheme to provide subsidies for the purchase of draught stallions." (d) "That the reduced freights in operation at the present time for the carriage of super be extended until the 1st of June." (e) "That before any further expense is incurred to make provision of carriage of heavy freight on the Tailem Bend-Adelaide Railway Line, a full investigation as to the possibility of a Southern or Murray Port be made." Resolutions c, d, and e were received.

*Agricultural Instructors Judging at Country Shows.*—The decision of the Hon. Minister disallowing Instructors to act as judges at country shows was received with regret.

*Resolutions from Conference of Southern Branches.*—(a) "That immediate steps be taken to call a Dairymen's Conference, where all phases of the industry can be discussed, and that the Conference be held in Adelaide." It was decided that the matter be left in the hands of the General Secretary to arrange a Conference at a suitable time and place, with Branches interested in the Dairying Industry. (b) "That the Advisory Board of Agriculture endeavor to arrange for a Conference to be held on Kangaroo Island, towards the end of March, 1931." The Secretary was instructed to bring the matter forward at the November meeting of the Board. (d) "That the destruction of African boxthorn be compulsory." (e) "That the wild or bitter melon be placed on the Noxious Weeds Act." It was decided to transmit resolutions d and e to the District Councils' Association. (f) "That the Dairy Cattle Improvement Act, 1921, be amended by substituting the words 'nine months' in place of 'six months' when referring to the licensing of bulls." It was decided to refer the resolution to the Dairy Cattle Improvement Committee. (g) "That this Conference strongly recommends that the present Government maintain the present agricultural institutions and officers and staff connected with the rural industry, which we consider is essential to the interests of the community and State in general, and we strongly urge the Advisory Board to bring this matter under the notice of the Government at the earliest opportunity." The Secretary was instructed to forward the resolution to the Minister with the indorsement of the Board. (h) "That discussions on subjects of economical importance to the man on the land, even though of political flavor, be allowed at Bureau Meetings." The Secretary was asked to publish in the *Journal* a statement pointing out that matters relating to phases of political economy could be discussed at Branch meetings, but such discussions must not be allowed to develop into debates on party politics.

## **BUNGEY BROS.,**

### **GRAIN and FORAGE MERCHANTS.**

**SPECIALISTS IN**—Baled Lucerne Hay and Lucerne Chaff.  
Compressed Fodder and Baled Oaten Hay.

**DEALERS IN**—Seed Wheat, Oats, Barley, Maize, &c.

**HEAD OFFICE: 178, FRANKLIN STREET, ADELAIDE. 'Phone Cent. 986.**

**Branch at Todd Street, Port Adelaide. 'Phone J 2190.**

**Wholemeal and Splice Grinding Mill, Symonds Place, Adelaide.**

*Subsidies for Crop Competitions.*—The Paruna Branch forwarded the following resolution:—"That this Branch protests against the action of the Government in discontinuing the subsidy on the crop competitions and asks the Department of Agriculture to approach the Government asking them to reconsider their action. It was pointed out that it was not a very big expense to the Government and asked for its continuance." The resolution was received.

*Location of District Instructor.*—At the Ceduna Conference a resolution was passed that the Agricultural Instructor for that district should be stationed in a more central position. The Secretary was instructed to advise the Branch that it was not thought practicable nor advisable to alter the present arrangements.

*Compilation of Records of Work at Blackwood Experimental Orchard.*—It was decided to defer consideration of this matter for another six months.

*Berri Experimental Orchard.*—The Berri Branch forwarded the following resolution:—"That this meeting of Monash and Berri growers fully appreciates the work that is being carried out at the Berri Experimental Orchard on behalf of the fruit industry, and that any curtailment of the good work being done there we view with alarm, as it would be a setback to the fruit industry along the river; and that a yearly grant be made to the Director of Agriculture to cover the necessary expenses in connection with experimental work at the orchard." The Secretary was instructed to forward the resolution to the Minister with the support of the Board, and to state that members note with pleasure this expression of confidence in the work being performed at the orchard.

*Services of Mr. A. V. Lyon.*—The Berri Branch also resolved—"That the Agricultural Department be approached through the Advisory Board asking them to move in the matter of getting Mr. Lyon on the Merbein Research Station to visit Berri and address the growers." As Mr. Lyon is a Commonwealth officer engaged specifically for research work, it was decided not to take any action in this matter. The Branch to be informed that as the results of the research work were made available the information would be published.

*Farm Book-keeping.*—At a meeting of the Streaky Bay Branch, held on July 25th one member spoke on the necessity of farmers keeping books, but considered that the usual system was too complicated for the ordinary farmer, and suggested that the Advisory Board of Agriculture endeavor to bring out a simplified form, suitable for farm business, and be a standard method. Agricultural Instructors to be asked to help farmers to use the method. It was decided to ask the Director to report on the request.

*Board Representation at Conferences.*—On the motion by Mr. Jeffrey, seconded by Mr. P. H. Jones, it was decided that in view of the financial position only one member represent the Board in an official capacity at future country Conferences. It was agreed that more than one member could attend, but that the Department would not be called upon to pay expenses other than for the member appointed by the Board to attend. In the case of requests which were received in the period between meetings of the Board for members to attend meetings of Branches, the Chairman and the Secretary were authorised to deal with the matter.

*Life Members.*—The names of Messrs. R. J. Rose (Laura) and V. Wake (Elbow Hill) were added to the rolls of Life Members of the Agricultural Bureau.

*New Branches.*—Approval was given for the formation of Branches of the Agricultural Bureau at Greenock and Warcowie (Women's).

## DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co., LIMITED, reported on September 1st, 1930:—

**BUTTER.**—The very favorable conditions in the dairying industry have resulted in a rapid increase in production, and this State for some weeks past has had a surplus, which is being exported to London. Last week substantial shipments were made by the *Mooltan* and *Esperance Bay*. The London market is weak and choicest quality is now quoted there at 124s. to 126s. per cwt., but sales are slow. This decline in price has been reflected in values here, and choicest quality in bulk is now realising 1s. 4½d. Second and third grades, 1s. 2½d. (These prices are subject to the stabilisation levies). Best separators, 1s. 1½d. to 1s. 2½d.; well conditioned stores and collectors, 10½d. to 11½d. per lb.

**EGGS.**—As usual at this time of the year, quantities are showing an increase each week, and this State now has a considerable surplus which is being taken up by pulpers and exporters. Already shipments to London have been made, and as both pulpers and packers are operating freely all consignments coming to hand have been cleared, and the market is steady. Ordinary country eggs, hen, 7d. per dozen; duck, 8d. per dozen.

**CHEESE.**—The season in the South-East promises to be exceptionally good, and it is expected that there will be a heavy milk production. Quantities arriving from the South-East are increasing each week, but with a steady local demand combined with a fair interstate sale, stocks are reasonably cleared. New makes, large to loaf, 8½d. to 8½d. per lb.; semi-matured and matured, to 1s. per lb.

**ALMONDS.**—Only small quantities are arriving, and there is a good demand for all shell lines. Kernels are also in good request. As most of last season's crop has been cleared, stocks are only light. Brandis, 8d. to 8½d. per lb.; mixed softshells, 7d. to 7½d.; hardshells, 4d. to 4½d.; kernels, 1s. 7½d. per lb.

**HONEY.**—Owing to fairly heavy stocks being carried in the other States, there has not been much exported from South Australia, and locally the demand is only fair. Sales are practically limited to prime clear extracted, and there is a surplus of lower grades which is difficult to quit even at low prices. Prime clear extracted in liquid condition, 4½d. to 5d.; best quality candied lots, 4½d. to 4½d.; second-grade honey, 2½d. to 3d. per lb.

**BEESEX.**—No alteration to report. Sales are slow, 1s. 5d. to 1s. 5½d. per lb. according to sample.

**BACON.**—There are ample stocks of bacon held by all curers at present, as supplies of live hogs to the markets have been good. Although the turnover is being steadily maintained in bacon, the demand for hams is somewhat slow. Best local sides, 11½d. to 1s.; best local factory cured middles, 1s. 1d. to 1s. 1½d.; large, 10d.; local rolls, 10½d. to 11d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 5d.; local, 1s. to 1s. 1½d.; "Sugar Cane" lard, in packets, 11d. per lb.; in bulk, 10d. per lb.; local lard, 9d. per lb. in prints.

**LIVE POULTRY.**—There has been a good demand for all classes of poultry during the month, and although our sales each week have been well supplied with consignments from the country and suburban yards, the demand has been sufficient to absorb all lots at satisfactory prices. We advise consigning. Crates loaned on application. Prime roosters, 4s. 6d. to 5s. 6d.; nice-conditioned cockerels, 3s. 6d. to 4s. 3d.; fair-conditioned cockerels, 2s. 7d. to 3s. 3d.; chickens, lower; heavy-weight hens, 3s. 3d. to 4s.; medium hens, 2s. 6d. to 3s.; light hens, 2s. to 2s. 4d.; couple of pens of weedy sorts, lower; geese, 4s. to 5s. 6d.; prime young Muscovy drakes, 4s. to 5s. 3d.; ducks, good conditioned, 3s. to 3s. 9d.; ducks, fair condition, 2s. to 2s. 9d.; ducklings, lower; turkeys, good to prime condition, 8½d. to 11d. per lb. live weight; turkeys, fair condition, 7d. to 8d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 6d. each.

**POTATOES.**—Prime Victorians Red Soil Snowflakes, 8s. per cwt.

**ONIONS.**—Best brown, 6s. per cwt.

A.M. Annual meeting.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

#### SOUTH-EAST DISTRICT.

**MOUNT GAMBIER** (Average annual rainfall, 30.82in.).

Meeting held June 13th. Present: 14 members. Mr. G. Gurry read an interesting paper, in which he gave an outline of the early history of the Mount Gambier Branch of the Agricultural Bureau.

**WOLSELEY** (Average annual rainfall, 18.36in.).

June 9th.—Present: 31 members.

**TRACTOR VERSUS HORSES.**—Mr. S. J. Baker read the following paper:—"First it is necessary to purchase a good, reliable make of tractor, which will cost approximately £500. The life of the tractor will depend on how it is looked after. If the manufacturer's instructions are followed a tractor should give seven to ten years of general farm work. After having worked the tractor for two years have the engine overhauled once each year. For the soil in this district one requires a tractor that will do at least a 10-horse job, and one that will work 24 hours a day when necessary. The cost of 10 horses, harness, stable, and feed for the first year would cost as much as a tractor and fuel for the first year. Tractor and fuel for the first year, £650. Horses:—10 at £30 each, £300; harness, £8 per horse, £80; feed, £20 per horse, £200; chaff, shed and stables for 10 horses, £100; total, £680. The tractor would be much quicker than the 10 horses, and time is worth considering. With tractor farming one would not require to employ so much labor as farming with horses. Ten horses would require approximately 50 acres for grazing per year. With a tractor this 50 acres could be cropped and show a good return. The attention that a tractor in working order requires would not be more than half an hour a day. With horses it is necessary to get up early to feed and groom; this is wasted time. When the ground is suitable for horses to work on it is suitable for a tractor, and, done with a tractor, has a better appearance, and there is not so much waste time. The tractor will not tire from heavy working. When a horse breaks down it must have a spell, and therefore a spare horse or two has to be kept on the farm. With a tractor small mishaps can be fixed up in very short time, and not much knowledge is required. When the day's work is finished a tractor is ready for duty the next morning, and does not want feeding."

**HORSES VERSUS TRACTOR.**—Mr. S. Snoad read the following paper:—"It is easier to start farming with horses than with a tractor, because of the difficulty of obtaining finance. Whilst horse-power is slow, it is steady, and there is not so much likelihood of breakdowns. There are farmers in this district who owned tractors, yet they work horses, and leave the tractor in the shed. A horse farmer can maintain his team by rearing one or two foals each year, and so keep the team young and active. The life of a tractor is only about five years. To obtain the best results from a tractor the machine should be worked by the same man the whole time. Probably the lack of experience in tractor drivers is one of the greatest obstacles at present in the way of successful power farmers. The person in charge of the engine should realise that a very delicate piece of mechanism has been placed in his hands, and that skill and attention are needed constantly if best results are to be obtained from the tractor. A team driver does not need any mechanical knowledge to manage and drive horses. The work of a team of horses is done silently and without the continual vibration which eventually affects the nerves of the operator of the tractor. A farmer can do the work much cheaper by having a good grass paddock for his horses for working the fallow. I worked 140 acres three times on one feed a day. The horses were got in in the morning from the paddock and worked until dinner time, and then turned out again in the paddock at night. They were in fat condition the whole time."

**HORSES VERSUS TRACTOR.**—The following paper, putting the claim for horse as being the most efficient and economic worker on the farm was contributed by Mr. E. Sharrad, who proposed to deal with farms of no more than 700 acres:—"This farm cannot be more efficiently worked with a tractor than with horses. In the Tatiara, in a normal

year, one has to do a certain amount of fallowing when the crabholes are full of water. The horses will do this job, as well as the hundred and one small jobs on a farm which require a horse. The horse has helped to buy most of the tractors on the farms. I have worked both the tractor and horses, and would rather drive the horses. The latter is a cleaner, warmer, and a quieter job. If one horse is sick it can be replaced at very little cost; one can perhaps borrow from a neighbor who has a few idle horses. If the same trouble persists in a tractor it is impossible to borrow another tractor, and one may possibly be hung up for a week or two in seeding or harvest, waiting for repairs. Most writers, when comparing the relative values of the horse and tractor, put too high a price on the horse. A half-draught horse can be bought for £10 or £15, which will do the work, and do it well. There is no necessity to pay high prices for horses. A young farmer starting on a farm on his own can aim at getting a good team by gradually raising the class of his team by breeding. Two good mares will breed up a team in a few years, and by always breeding a couple of foals every year it will not be necessary to pay high prices to fill up the gaps in the team, occasioned by old age and the loss of a horse. The cost of keeping a foal is very light until it is ready to break in. After paying for the service of a good sire, there is practically no expense until it is time to break in the foal, and then only at a cost of about £3 10s. for harness, which, if carefully looked after, will last for 20 years. The heavy initial cost of the tractor gives the farmer a good deal of worry wondering if he is going to pay for it. The tractor is a continual drain on the finances of the farmer for grease, benzine, and kerosene all through seeding and harvest. Money is sent out of the Commonwealth for the tractors and all that propels them comes from overseas. The horse and all its harness are products of Australia. It should be the aim of all farmers to build up the Commonwealth by using horses, thereby effecting a saving of money."

**TRACTOR VERSUS HORSES.**—Mr. A. Grosser read the following paper:—"The tractor has its advantages and disadvantages. If farmers would realise that the power of a tractor is limited to pull a certain load it would give far better results. The life of a tractor depends on the treatment it receives. One does not hear of a farmer going out with an eight-horse team and pulling two ploughs with it; yet this is not uncommon with the tractor. The most important point to watch is the oiling. Also water and grease the cups, and keep all bolts tight. The tractor is able to take the place of an engine for cutting chaff, and can be used to assist in putting in and taking off the crop at a critical stage. Horses have to be given a spell, but the tractor, with proper care, will work continuously. It can also be used for pulling trees and pumping water. The tractor is worthy of a place on the farm. Those in the past who were not in favor of tractors have one to-day."

**HORSES VERSUS TRACTOR.**—"There is no doubt that the tractor has its good points, but, from my experience, horses are the best all-round form of farm power," said Mr. H. W. Orton, in a paper on this subject. "Australia produces its own horse-power, and by using this power we are helping ourselves. The tractor is made overseas, the fuel is imported, and the money goes to other countries. It is argued that the tractor will sow twice as much area as a team of horses. This is possibly true, if everything goes well; but in the case of a breakdown with the tractor it will mean perhaps the loss of a week before the part is replaced. If a horse becomes sick, at a pinch it is possible to carry on with one less, but generally there is a spare horse on the farm that can be used until the sick one recovers. If at fallowing the ground becomes wet and the crabholes boggy, the horses are able to get along, but the tractor bogs and makes a poor job of fallowing. At harvest it does not pay to work the tractor half-loaded, and the average-type is not more than half-loaded when pulling a harvesting machine. This is waste of fuel. It requires two men to operate a tractor and stripper; one can drive a team of horses and work a stripper, and there is no danger of fire with horses. When carting wheat, horses load the wagon with the bag-lifter, which would be a very tiresome job for the tractor. The feed which the horses eat for the year does not cost the farmer a great deal to produce, but fuel which the tractor uses requires money to procure. Tractor driving is a strain on the nerves, but it is a pleasure to drive a team of good horses."

## UPPER-NORTH DISTRICT.

### (PETERBOROUGH AND NORTHWARD.)

**BLACK ROCK** (Average annual rainfall, 12.57in.).

On June 17th a debate, "Horses v. Tractor," was held between teams from the Morchard and Black Rock Branches. The Morchard Branch, which debated in favor of the tractor, was adjudged the winners.

**MORCHARD** (Average annual rainfall, 13.50in.).

At the June meeting of the Branch Mr. P. Schultz read a paper, "Domestic and Farm Animals." The annual report was read, and officers elected for the ensuing year.

**QUORN** (Average annual rainfall 13.60in.).

Mr. L. Eckert gave an address, "Misplaced Methods of Farming in the North," at the meeting held on June 11th, which was attended by eight members.

**WARCOWIE** (Average annual rainfall, 12.16in.).

June 10th.—Present: Nine members and four visitors.

**HINTS ON SOLDERING.**—Mr. A. Crossman read the following paper:—"A knowledge of soldering will often prove useful on the farm. Two irons are needed—a heavy one weighing about 1lb., and a lighter one for fine work. Use good solder. A brush for applying spirits of salts can be made with a piece of tin and horse hair. For new and clean galvanized iron the spirits can be diluted with water, but where the material to be soldered is dirty, use raw spirits, leave it for a few minutes, and then rub off with a rag. Do this until the material is clean. Although sometimes this will not bring everything off, the dirt can be scraped off with a piece of an old wire rope a few inches long. Tightly fasten a piece of tie wire near the ends and rub with the ends. The fine wire will find its way into small cracks. Sal ammoniac is used for tinning the iron. When the iron is fairly hot, rub the point with an old file to clean it, then rub on the sal ammoniac, melt a little solder on it, turn the iron in this, and no trouble will be experienced in tinning, providing it is clean and smooth. Have the iron hot enough to melt the solder quickly, but do not get it red hot or the tin will be burnt off. When making a joint, see that the solder is sweated in between both pieces, and watch for air bubbles. In soldering brass, I find that resin or soldering preparation is much better than spirits of salts."

**WEPOWIE** (Average annual rainfall, 13in. to 14in.).

Mr. T. Orrock presided over an attendance of nine members and visitors at the meeting held on June 30th, when a paper, "Buy Australia Made Goods," was contributed by Mr. E. Rooeke.

---

## MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

**BOOLEROO CENTRE** (Average annual rainfall, 15.41in.).

Mr. E. L. Orchard (District Agricultural Instructor) delivered an address, "Fallowing and Wheat Varieties," at the meeting held on June 17th, which was attended by six members.

**KOOLUNGA** (Average annual rainfall, 15.61in.).

Meeting held July 1st. Present: 14 members. Mr. Campbell, of the Royal Automobile Association, delivered an address.

**KOONUNGA.**

A paper, "Oil and Some of Its Uses," was read by Mr. G. Cartwright at the meeting held on March 11th, which was attended by 24 members.

Twenty-two members attended the meeting held on April 8th, when a paper, "Pig Raising," was contributed by Mr. A. Tscharke.

At the meeting held on May 13th Mr. W. Mickan gave a demonstration of soldering. Twenty-one members attended.

**KOONUNGA.**

Meeting held June 10th. Present: Mr. R. Tscharke (Chair) and 30 members. Mr. W. Mickan delivered an address, "The Lack of Co-operation between the Farmer and the Blacksmith." An interesting discussion followed.

**MOUNT BRYAN** (Average annual rainfall, 16.87in.).

Meeting held June 14th. Present: Eight members. The meeting took the form of a Question Box. A number of interesting questions were asked and discussed.

## MURRAYTOWN.

Meeting held June 7th. Present: Mr. F. Bleischke (Chair) and 14 members. Mr. E. L. Orchard (District Agricultural Instructor) gave an address, "Fallowing."

REDHILL (Average annual rainfall, 17.02in.).

Meeting held June 10th. Mr. T. Simmonds presided over an attendance of nine members. Mr. S. Crouch read a paper, "The Care and Management of the Farm Horse," and a good discussion followed.

SNOWTOWN (Average annual rainfall, 15.78in.).

There was a large attendance of members at the meeting held on June 13th, when Mr. C. Crewe, of the Vacuum Oil Co., gave a cinema lecture entitled "Lubrication."

## WANDEARAH.

Meeting held June 10th. Present: 21 members. Mr. L. Crouch delivered a short address, "Points in Successful Wheat Growing." Members submitted questions, and several discussions took place. Items from the *Journal of Agriculture* were read and discussed.

WIRABARA (Average annual rainfall, 19.47in.).

April 10th.—Present: 17 members.

KEEPING A FARM DIARY.—Mr. A. Curtis read the following paper:—"This paper is written with the idea of pointing out the value of continual record of activities during seasonal work. One is prone to think that no records are needed as, for instance, the day seeding is started, but if one had records of the dates, say, for a period of 15 years on which seeding was started, together with the results, it would probably help one to come to a decision as to whether it would be advisable to go on or not during some abnormal season. Many farmers have no doubt read with interest various articles that appear from time to time in the *Journal of Agriculture* on "Crop Rotation" or some kindred subject, but could individual farmers write down in correct order the rotation in which the paddocks have been cropped and which crops—wheat, barley, oats, &c.—bare fallow, grass or stubble, quantity of super used, name of wheats, rainfall, &c., that have been sown on the paddocks. If these details are lacking, how is it possible to draw correct conclusions from any rotation of crops that may be attempted. Even if entries are made only at regular intervals of a week or month it would be of great service. After a copy is full, a year's remarks in brief can be appended. There is usually a page for this purpose at each end of a volume. The blotters in the diary are very useful, the book is a good calendar, and contains useful information to the user. To no one should the keeping of a diary be of more service than to farmers and other primary producers."

THE ARTESIAN BASINS.—A paper of this subject was read by Mr. H. Hunt at a meeting held on May 8th:—"The Continent of Australia is like a saucer in shape. It is high round the coast, and hollow in the middle. The water which falls in the high lands near the coast soaks down into the layers of rock which form the earth's crust. These layers are of two qualities, the impervious hard rock, and the pervious, soft sandstone rock. Often, as in the case of the Great Australian Basins, the soft rock is underneath a layer of hard rock, so that until a bore is sunk through the hard layer the water cannot come to the surface. When the water does come to the surface it comes with great force, and often shoots up high in the air. In the Great Australian Basin these layers of rock are curved downward in the centre, their outcrops being in the high lands on the east coast of Australia, which is the intake, and near the railway where the water rises to the surface and is evaporated, leaving mounds of mineral with water on their summit in a basin. Some of these mounds are 60ft. in height. Bores are, of course, sunk between these outcrops. The depth of the bore depends largely on its position in the basin. Near the outcrops 50ft. may be sufficient, but the bore at Blackall, near the centre of the basin, is 7,000ft. deep. The yield from one bore for 24 hours has been known to reach 3,000,000galls. There are 1,300 bores in the Great Basin, 50 of which are in South Australia. Water from deep bores is hot and highly mineralised, fit only for stock, except in rare instances where it has been found to be suitable for irrigation. The flow from many of the bores is decreasing, and measures for controlling the water have been taken. The main vegetation in this area is drought-resisting plants, such as salt bush and blue bush, although in many parts grass grows. There are three fairly large ones in Western Australia, one around Eucla, and a large one in the Murray Basin. There are several small ones in South Australia, including one in the Orroroo district."

**LOWER-NORTH DISTRICT.  
(ADELAIDE TO FARRELL'S FLAT.)**

**BLACK SPRINGS.**

Mr. W. J. Spafford (Deputy Director of Agriculture) delivered an address, "General Farming Practices," at the meeting held on June 12th, which was attended by 16 members.

**BROWNLOW.**

Meeting held June 25th. Present: 18 members and visitors. Mr. S. B. Opie (Field Officer of the Department of Agriculture) delivered an address, "The Value of Experimental Work."

**LIGHT'S PASS.**

Meeting held June 16th. Present: 33 members. Mr. W. Sharp gave an interesting lecture, "The Early History and Colonisation of South Australia."

**PENWORTHAM.**

The Annual Meeting was held at Sevenhills on June 19th, and was attended by 20 members. The annual report was read, and officers elected.

**ROSEDALE.**

Nineteen members and visitors attended the meeting held on June 17th, when Mr. J. Ruediger delivered an address, "Pruning Fruit Trees and Vines."

**ROSEWORTHY (Average annual rainfall, 17.46in.).**

There was a large attendance of members and visitors at the meeting held on June 5th, which took the form of a debate on the subject, "Open Marketing v. Pooling Wheat." Open marketing was debated by Messrs. E. Rice and P. Maloney, whilst the claims of the pool were supported by Messrs. E. Oates and J. Dridan. Members were present from the Gawler, Wasleys, and Mallala Branches.

**TARLEE (Average annual rainfall, 18.16in.).**

At the meeting held on May 13th, the Chief Dairy Instructor (Mr. H. B. Barlow) delivered an address, "The Dairy Industry Act." Seven members and four visitors attended.

**WASLEYS.**

Fifty-two members and four visitors attended the meeting held on June 20th. Mr. R. Baker, R.D.A. (Dairy Instructor at Roseworthy Agricultural College) delivered an address, "The Care and Management of the Farm Cow."

**WASLEYS WOMEN'S.**

Mrs. F. Wait presided over an attendance of 41 members at the meeting held on June 5th. The following papers were read and discussed:—"Bacon Curing on the Farm," Mrs. F. Napper; "Cake Making," Mrs. Carey; "Making Small Cakes and Biscuits," Miss I. Sires. Samples of cakes, &c., were tabled by the readers of the papers.

**WILLIAMSTOWN WOMEN'S (Average annual rainfall, 27.84in.).**

Meeting held July 2nd. Present: Eight members. The Annual Report was presented and officers elected for the ensuing year.

**YORKE PENINSULA DISTRICT.**

**(TO BUTE.)**

**THRINGTON.**

June 5th.—Present: 23 members and four visitors.

Mr. M. Yelland read a paper, "Side Lines on the Farm":—South Australia was principally an agricultural State, wheat being regarded as its chief asset, but there was no reason why it should not be self-supporting in other essential products which were termed side lines. The last year or two had made the farmer realise what a stand-by they were to wheat-growing. Every farm should have side lines, but the extent to which they could be worked depends on the size of the farm and how the farmer was situated. The man with a grown family was better able to run side lines than a man who was a bachelor or who had only his wife to assist him. The main thing with side lines was

to provide proper housing and accommodation for all stock; that was half the battle, and without it there was little chance of success or profit. The most profitable side line in the district was sheep. Besides the financial return, sheep were a valuable asset in keeping the fallow clean, and they also packed and consolidated the seed-bed for the coming crop. By buying and selling sheep one might receive good returns, but one was liable to become overstocked, and if the market fell they would have to be carried on, which would restrict fallowing operations and result in lower crop yields the following year. On the average farm in the district it paid better to keep a permanent flock of from 150 to 200 large-framed Merino ewes, keeping only enough wethers for killing purposes. The Merino ewes could be crossed with some ram suitable for breeding fat lambs, such as the Shropshire, Dorset Horn, Leicester, Lincoln, or the Corriedale. He favored the Corriedale because the wool was of better quality and the lambs were good for mutton. The ram should be mated early in November and the lambs would arrive in April in the warm weather, which would be much better for the young lambs. While the ewes were lambing they should be looked at every day or two, especially if flies were bad, and should always have plenty of feed and water. With good luck, with 150 ewes one ought to get about 120 lambs. Besides the lambs, one would have the wool from the 150 ewes. At shearing time one should cull out any that were poor-woolled or were fencers. They could be killed off. With sheep on the farm, meat was always procurable for about half the price it could be bought from the butcher. Pigs were profitable, especially since the price of barley was low. Some farmers bought two or three suckers and reared them and then sold and re-stocked again, while others kept four or five breeding sows and a hog. Regarding breed, it was just as costly to feed a good animal as a mongrel; they ate just as much feed, but there was not nearly the same profit. The Mid-York cross was very good, or Berkshire or Mid-York sows crossed with the Tamworth; and again, Berkshire or Mid-York crossed with the Large White York. That was the pig advocated at present for a bacon pig, and was strongly recommended by the Victorian Better Farning Train. The Tamworth-Berkshire made a fine bacon pig, or again, a three-quarter Tamworth mated to a Berkshire hog, or *vice versa*. There should be three or four sties—one kept for the hog and the others for the sows. It was a good thing to have about an acre or two pig-netted and sown with barley. The pigs would graze on it in the winter, and it would form the bulk of their food, especially sows that had been mated, which should always have plenty of water, and in the summer time should have a wallow with plenty of water in it. Barley was about the best feed for pigs. For best results it should be crushed; if not crushed it should be well soaked or boiled, otherwise the pigs did not obtain the full benefit from it. Each sow should have two litters a year of from eight to ten pigs; some had more. Calculated at £1 per head, they would be very profitable. The sow should be put in a sty to herself about a week before farrowing, and kept fairly quiet. The sty should have a railing around it, so the little pigs could get out of the mother's way. Straw should never be put in with a sow before farrowing, but always a little chaff or something not too bulky, because when the pigs were born they were either suffocated in the straw or the sow lied on them. Straw could be put in after about a fortnight. If one was about when the sow farrowed, it was advisable to take the pigs and put them in a box lined with bag and keep them warm until they were all dry, and then put them back with the sow and see that she suckled them. A sow should not be fed much for about 24 hours after farrowing. After that she could be fed regularly. After about a fortnight the little ones would drink a little pollard and milk, mixed thin, in a small trough. At about three weeks to a month all pigs should be doctored. The knife should be clean, and salt water applied to the wound after doctoring. When done, the young pigs should be put into a clean sty with a concrete floor. If they got dirt into the wound they would be liable to get tetanus. When the pigs were six weeks old they should be weaned and would be fit for sale. Lice could be kept off the pigs by using tractor drainings and kerosine or sheep spray for blowflies. The fowl on the average farm did not receive much attention with the exception of a little wheat now and again and a tree to roost in. Most of them were of the barndoor variety. The first step with fowls was to house them in good houses, which should be anything from 12ft. to 15ft. deep, with a vent at the back for draught, and should have netting around them and doors so that fowls could be shut up at night against foxes, dogs, cats, &c. Tick was one of the bugbears of poultry-raising, but could be controlled by tick-proof perches and weekly applications of sump oil and kerosine on perches and all woodwork. Nests should be made out of tins, and should have beach sand or chaff put in them. He favored the White Leghorn or the Minorca for egg laying. Orpingtons were very good, and the Rhode Island Red made a good table bird. Fowls should always have plenty of shell grit and charcoal, and also plenty of green food. Greenfeed was one of the most important things with fowls. Lucerne was the best, and could be easily grown where one had plenty of water. For feeding fowls, he favored crushed barley mixed with bran. A good mash was two parts of crushed barley and one part bran, with plenty of chopped-up

lucerne, or barley fed whole was very good. If fed properly fowls should return about £1 a hundred per week profit. All eggs should be gathered at least once a day. Roosters should not be allowed to run with the hens that were laying for market. If farmers generally were more particular with farm eggs they would receive a better price all through the year. He favored the incubator for breeding chicks. About the 120 size was convenient on a farm. All eggs should be not over a week old for incubation. Care should be taken with the incubator with regard to the temperature moisture and to see that it was level and to run it in a suitable position without draughts. When the chickens were taken from the incubator they should be put into a brooder. Suitable pens for brooding should be made, with wire-netting runs outside for use on sunny days. Chicks should not be fed for 48 hours, and then fed on cracked grain, with plenty of green food and water. When they were about six weeks old they should be put in cold brooders and not overcrowded. When old enough, pullets should be separated from the cockerels, and the latter fed up and sent to market as soon as possible. Each year's rearing should be marked by a ring on the leg. In that way one would be able to cull

## VEGETABLES

*good health demands them!*

Only by eating vegetables frequently can we maintain our blood in good condition, and therefore, our health. This fact is not sufficiently realised.

Made in handy tablet form, Swallow & Ariell's Compressed Vegetables are equal in every way to fresh, as only water is removed, and their true flavour is retained. Easily prepared and economical—one pound of the compressed article goes as far as ten of the fresh—they take up so little space that they're easily stored.

With this product of Swallow & Ariell at hand you need never be short of health-giving vegetables. Buy a few packets now!

**SWALLOW & ARIELL'S  
COMPRESSED  
VEGETABLES**

the flock. After a hen had finished her third laying season she should be fattened and sold. The best way even on a farm was to keep fowls on the intensive system, keeping them shut up and fed properly. They would produce more eggs, especially during the winter months. Drinking vessels should be kept clean and houses cleaned out or the fowls would get roup. Epsom salts put in the drinking water once a week, and also Condy's crystals, would help to combat disease. The best time of the year to hatch the heavy varieties was July to August, and the light varieties from August until October. Autumn hatched chicks thrived well if they had plenty of green feed. Geese and turkeys on the farm were profitable, especially about a dozen young gobblers. Geese were very easily reared and picked up the bulk of their food, but they were very destructive. Turkeys were fairly difficult to rear, and they needed plenty of green feed. A hen was better to rear turkeys than a turkey hen, because the hen did not wander as a turkey did. Young turkeys should be fed on rolled oats for the first three or four days and then fed on bran and pollard mixed with warm milk to make it crumbly. Plenty of green feed and onion tops were also very good. Cows on the farm were all right if one had a family to do the work. Every farm should have one or two cows for home use, and one could then sell a little butter. Cows were a lot of work and were a big tie for the women on the farm. The best milking cow was the Jersey or the Friesian. In our district it was necessary to use so much dry feed for cows they did not get the results they would if there was green feed available practically all the year round. A big advantage of having two or three cows on the farm was the separator milk, which was of great value to young pigs. A good discussion followed.

#### WEAVERS (Average annual rainfall, 17.03in.).

June 9th.—Present: 17 members.

The evening took the form of a Question Box. Mr. L. Arthur asked, "Is it necessary to pickle barley when sowing under dry conditions?" Mr. Piggott considered pickling necessary if the seed was smutty. Mr. Slade said it was safe to sow grain dry if there was smut present, but as a preventive he advised using  $\frac{1}{4}$  per cent. solution of formalin. Mr. W. Anderson said it was safer to pickle barley under present marketing conditions. Mr. G. Tarrant asked the best method to adopt when breaking in young horses? Mr. L. Arthur thought the more handling the colt was given the better. Mr. Piggott advised putting on the halter with the bit in the horse's mouth, and allowing the colt its freedom to harden the mouth. The Hon. Secretary (Mr. H. Cornish) read the Annual Report, and officers were elected.

### WESTERN DISTRICT.

#### CLEVE (Average annual rainfall, 14.63in.).

The annual meeting of the Branch was held on July 2nd, there being present 10 members. The Annual Report was read, and officers elected for the forthcoming year.

#### ELBOW HILL (Average annual rainfall, 11in. to 12in.).

Meeting held June 11th. Present: 11 members and four visitors. Mr. H. D. Adams (District Agricultural Instructor) delivered an address, "Soils and their Management."

#### GOODE WOMEN'S (Average annual rainfall, 10.20in.).

Meeting held June 12th. Present: 13 members and 11 visitors. Dr. C. Hallett, M.B., B.V.Sc., delivered an instructive address in which he dealt with the subjects, "Anti-Natal Care" and "Child Welfare."

#### MALTEE.

Meeting held June 12th. Present: Mr. J. Bassham (Chairman), nine members, and three visitors. After formal business, the holding of a local Crop Competition was discussed, and it was decided to limit entries to Branch members only. Mr. Miller offered a shield to be competed for and the winner's name to be added each year. Mr. Schwarz exhibited a novel shoot-cutter made from an old disc drill.

#### MILTALIE (Average annual rainfall, 13.89in.).

Meeting held June 7th at the residence of Mr. J. Story. Present: 16 members and five visitors. An instructive paper, "The Value of the Primary Producer to Australia," was read by Mr. G. Partridge.

**STREAKY BAY** (Average annual rainfall, 14.95in.).

The meeting of May 25th was devoted to a discussion on matters of local interest. Five members attended.

On June 21st Mr. W. Johnston (Agricultural Instructor for the Lower North) addressed the meeting.

A large number of visitors and delegates attended the July meeting, when a lecture and demonstration was given by a representative of the Vacuum Oil Company.

**TARAGORO.**

June 12th.—Present: 13 members.

**POWER FARMING.**—Mr. S. Simmons read the following paper:—The increased efficiency that has resulted from the spread of improved machinery and larger power units, and the wider application of improved practices will be a strong influence in restoring agricultural prosperity in South Australia. Machinery, such as we have at our disposal at the present time, is causing a revolution in agriculture. What its results will be it is impossible to state, but it is evident that in the very near future definite changes are inevitable. The tractor is one of the most modern machines that has been introduced to agriculture of recent years. Production in quantity and labor-saving devices are what are needed to-day in agriculture, as well as in other industries. To do this, modern methods of working the farm must be adopted to ascertain which is most profitable. I consider the tractor the most efficient power for farm work, providing it is given proper attention. The progress that has been made in the quality, performance, and usefulness of the tractor in the last few years has been very rapid. It is a mistake to expect a tractor which is rated at 10 or 12 horse power to do the work or operate a load that it would take 14 horses to pull, and this is what occurs in many cases; overloading the tractor is the worst abuse to which it can be subjected. A "horse-power" as used by mechanics and engineers is a measurement of the rate of doing work—it is not merely a measurement but a force, exerted through a distance, and the time during which such force is exerted. It may be that a tractor is pulling the same load as is pulled by five horses, but that does not mean that the tractor is not developing more power than the horses. The speed at which the load is pulled must be considered in order to compare the relative amount of power developed. If the horses pull the load two miles an hour and the tractor pulls it four miles an hour, the tractor is developing twice as much power as the horses and doing twice as much work. That is why a tractor rated at 10 horsepower on the drawbar and only pulling a load equivalent to five horses is developing its full rating of 10 horsepower. A horsepower is a fixed unit which does not vary. There are many and varied branches of work which a tractor can do. It does belt work as well as field work. It requires no care when idle, it is not affected by heat or cold, needs no rest, is unfeeling under neglect and hard work, and does faster work. That is where the tractor has an advantage over the horses. Time is a very important factor on the farm, and time saved is time gained. Not only does it enable the farmer to do his work much faster, but he is also able to take advantage of weather conditions. A tractor can be worked both by day and night if so desired. Providing it has the three essentials—fuel, oil, and water—the tractor will work indefinitely. This cannot be accomplished with animal power; muscles must have a rest. An animal body, be it man or horse, is capable of developing a certain amount of energy only every 24

hours. Muscles cannot produce power continuously for more than a few hours at a time; they must have rest to allow them to recuperate. On the other hand, an engine such as is built in the tractor of to-day is capable of delivering its full rated power not only hour after hour, but week in and week out. The owner will be confronted with minor troubles and mishaps, but after a person becomes conversant with the mechanism of the engine these will be speedily put right. Where a tractor can be used on a farm it will prove to be an asset, by enabling the farmer to keep abreast of the times, and will encourage better and more modern methods of working the farms." Discussing the paper, Mr. J. Crooks thought the tractor in conjunction with horses was a good combination where feed was grown on the farm, the tractor to do the heavy work and horses the light work. Mr. E. Retallick said a farmer should consider the cheapest method for working. He preferred horses when established, but advocated the tractor for a new block. Mr. T. Winters thought power farming too expensive, and favored horses worked in conjunction with a tractor. Mr. I. Guy preferred six horses as well as tractor; the horse team could do drilling and follow the tractor. Recently with his tractor and a 14-tine cultivator working day and night he had completed 330 acres in a week. Mr. A. Edwards said the tractor was not as cheap or reliable as horses. Horses worked in conjunction with the tractor was an ideal combination. Mr. T. Winters said provided the farm was suitable for a tractor and careful attention paid to maintenance and using suitable implements, the tractor would prove an asset. By rushing in the crop at the most suitable time the returns would compensate the working costs. The price of fuel and lack of efficient service stations in country districts were very serious drawbacks to tractor owners. Tractor farming, despite those drawbacks, had many advantages which could not be overlooked. The life of a tractor depended on the class of country on which it worked and its driver.

#### WARRAMBOO.

May 13th.—Present: 30 members and four visitors.

**FALLOWING.**—Mr. O. J. Murphy read the following paper:—"Various systems of farming have been adopted with the object of producing heavy crops and of maintaining and increasing the fertility of the soil. In certain districts of this State, where the average rainfall is not less than 20ins., successful results are being obtained by a crop rotation in which the growing of peas is an important factor. But in respect to the greater part of the Australian wheatgrowing areas, the practice of bare fallowing has been found to be the most effective system in the production of food crops. Fallowing means that for a period of approximately one year, part of the soil is lying practically idle. We must ask ourselves, therefore, why this practice is adopted, and how it tends to maintain the fertility of the soil. It has been proved that a crop of peas obtains a considerable amount of its nourishment from the air in the form of nitrogen, and stores it in the soil. The succeeding crop of wheat benefits by this process, termed the nitrification of the soil. Any system of farming which does not provide for the maintenance of the fertility of the soil must fail ultimately. In what way does fallowing bring about the nitrification of the soil, and the maintaining of a high state of fertility? In answer to these questions it may be said that no other system in Australia has been so productive of good results as the practice of fallowing. The main objects of fallowing are the conservation of moisture, the aeration of the soil, and the production of those special conditions which are distinctly favorable to the vigorous growth of the wheat plant. It has been shown that the conservation of moisture is by no means the only important factor. Agricultural scientists inform us that there is a tremendous amount of bacterial action in the soil which has an important bearing on the fertility of the soil. When we fallow land and use good cultivation methods at the right time we provide conditions which are favorable to great bacterial activity. The average farmer may not understand the action of soil bacteria, but scientists tell us that the results of bacterial action in the soil is practically the same as the results which follow the growing of a pea crop. Any system of cultivation which will stimulate bacterial action means greater fertility of the soil, and correspondingly greater crops. Both moisture and heat are necessary for rapid bacterial action, but it should be again emphasised that the moisture content of the soil is not the only important point. Dr. Richardson has stated that 3½bush. of wheat per acre may be grown under favorable conditions for every inch of rain which falls during the growing period of the wheat plant. This fact has been demonstrated on South Australian farms within recent years, but the fact that the average crop falls very far below this standard indicates that moisture alone is not, perhaps, so important as we were inclined to think. We must have other conditions favorable to the wheat plant's growth, and fallowing helps to provide these conditions. In regard to the question of fallowing on the West

Coast, and in our district in particular, there appears to be sound reasons for the adoption of a regular system of fallowing. Our average rainfall and the conditions which obtain in new mallee areas do not warrant the testing of a rotation of crops in which peas may be grown; but if we fallow our land, we can in the first place conserve moisture. We can all recall seasons when the prospects for a good harvest were excellent until a dry spell in the spring months occurred. The weather conditions of the spring apply the acid test to our crops, and the best safeguard against a crop failure at that time of the year is a well-prepared fallow. *Methods of Fallowing.*—The writer advocates the use of a rigid tyne cultivator or skim mouldboard plough for the initial stirring of the soil, with a preference for the cultivator on comparatively new lands. A cultivator with wide tynes, good clearance, and lever to adjust draught while working, specially designed for use in the mallee areas can now be obtained. It does excellent work, and covers more ground per horse than the plough. The work should be shallow, not more than 3in. in depth. Long experience goes to show that the wheat plant thrives best on a shallow, well-compacted seedbed covered by a loose mulch 2ins. or so in depth. Fallowing should be commenced as soon as possible after seeding. Rain is one of the best agents in compacting the soil. Early fallowing has, therefore, two great advantages over late fallow in respect to conservation of moisture and the compacting of the seedbed. Most of the land in this district may be described as fine-textured sand rises, and heavier, red, loamy flats. If the sand rises can be worked when the soil is wet, so much the better. Subsequent working of the fallow will depend on seasonal conditions. It should always be borne in mind that the value of fallow depends not so much on the amount of cultivation as on the time at which the work is carried out. The growth of weeds may be kept in check by sheep. If these are not available, cultivation should be done with the rigid-tyne cultivator before weeds have seeded, and preferably after a rain. Harrows may be used on the heavier soils with advantage, but should not be used on sand rises. The latter should not be worked in a dry condition on account of the drift menace. Drift takes place readily on a smooth, level surface. In the event of heavy rain, such as the 24in. which fell in December last, the surface of the fallow may be washed over. Immediate working of the fallow after summer rain of this character will check the tendency to drift, caused by the smoothing action of the rain, and will also prevent rapid evaporation of moisture from the seedbed. Moisture rises to the surface by capillary action, in the same way that moisture rises through the bark of the tree. If we could cover our soil with cocky chaff or stable manure immediately after a rain, we know from experience that we could retain a large percentage of the moisture, but as that method is not practicable, we use the cultivator or the harrows. The working of the surface of the fallow after rain makes a break in the capillary action of the moisture, and although the cultivation may result in the more rapid evaporation of moisture from the immediate surface, we form a mulch which prevents rapid evaporation from the seedbed. Sandy soils are self mulching, and although action is not necessary to produce a fine mulch, it should be carried out more with the idea of preventing drift. Hence the great importance of cultivation after rain. Apart from the question of conserving moisture, forming a seedbed, and working the fallow with discrimination, there are other important points in favor of fallow in new areas. It is the aim of every mallee farmer to free his land from mallee shoots and stumps. It is practically impossible to make a thorough job of seeding operations if we leave the whole of the cultivation until seeding. In fact, the amount of work involved in ploughing or cultivating at seeding time, removing stumps pulled out, drilling and harrowing, is so great that less thorough methods are frequently resorted to in order to crop a big area. Fallowing enables the farmer to spread the work throughout the year—it will result in more stumps being removed from the soil; the prospects of a good stubble burn so necessary in eradicating the mallee shoot will be considerably enhanced, and as a consequence, the period of reclaiming the soil from the mallee will be appreciably shortened. Moreover, the farmer who has land fallowed can afford to choose the most favorable part of the season in which to sow the land. Any attempt to sow a large area at seeding time not previously prepared must result in at least a portion of the crop being sown very early or very late. The very early sown crop is more liable to damage by drift. The crop grown on fallow will show the effect of a heavy application of super; it will be a very poor year in which the crop on fallow will not pay expenses. In respect of the question of fallowing virgin land, there is not sufficient evidence to show whether this practice would be payable, but the new settler would be well advised to start a fallowing system in the second year of his block. Five hundred acres of land yielding 12bush. to the acre will not give any more bags of wheat than 1,000 acres yielding a 6bush. average, but the former is a very much better proportion from an economic point of view. Once adopted, the practice of fallowing will soon induce the farmer to aim at average, rather than area." *Fallowing.*—Mr. W. Norris read the following paper:—"One of the most

important roads to success on the farm is fallow. According to statistics, wheat reaped off fallow in 1928-29 yielded an average of 12bush. per acre, while wheat off land not fallowed averaged 6bush. per acre. When fallowing, it should be seen that the plough is kept in good order, thus turning over the furrows evenly and cutting all the ground between the furrows. The shares should be kept sharp, never allowing the bodies to rise. Fallowing should be commenced in June, and finished no later than the 20th August. Late fallow has a tendency to create take-all; the depth of the fallowing should vary according to the nature of the soil. I will divide the land into three classes—heavy, medium, and light. Heavy soil should be ploughed 3in., medium 2½in., and light 2in. All land that is not sandy should be harrowed as soon as possible after ploughing in order to pack the soil and start the germination of weeds. After the first good rain has fallen and weeds have germinated, the land should be cultivated with a narrow tyne cultivator, in order to kill the weeds that have germinated, and increase the bacteria in the soil. After the next good rains have fallen and the land is beginning to dry on top, it should be harrowed again. Fallow should always be harrowed after every good rain, never allowing the land to crust on top. This acts as a blanket, preventing the moisture from evaporating." In reply to a question, Mr. Murphy said if it was possible to control the drift it might be as well to allow the sand from the ridges to drift down on to the flats. Once this sand started to drift it was practically out of control. The ridges should be worked with a rigid-tyne cultivator, and left in a rough state to try and prevent them from drifting, and to conserve moisture. Mr. J. Sampson advised fallowing the sand hills to a depth of 3in. or 4in. He had dealt with some of the sand hills on his farm last year in this way, and found that the hills did not drift so much after this treatment. Mr. O. Murphy said when fallowing a piece of ground last year he left a portion of one sand hill uncultivated, and noticed after the heavy rains in December that this piece of land was continually on the drift, worse than any other piece of land on his farm. Mr. O. Wagner considered that a rotation of crops would turn out fairly well on an average, although this would need to be very closely tested for a term of years.

#### WARRAMBOO.

June 10th.—Present: 22 members.

**CARE OF FARM HORSES.**—Mr. J. Sampson read the following paper:—"Horses should be provided with a warm stable, and plenty of good feed and water. If it is not convenient to build a stable, a shelter can be provided. Also provide the team with well-fitting harness, and give it an occasional dressing of oil. Groom them before harnessing, and on the first sign of a sore shoulder the collar should be eased, which will perhaps enable the horse to be worked, and at the same time heal the sore. Most troubles start in the first place with the collar being too big. I find cutting the fold off the top of a wheat bag and doubling it and putting under the collar, and if one is not enough, put two, and so on until the collar fits firm on the neck. By no means let it work on the neck—that causes the collar to chafe. A good plan is to soak a new collar in water before putting it on, and that will pull into the right shape on the horse's neck. See that the collar is clean before putting it on, and that the horse's neck is clean. Never bring in a horse out of the paddock and put him on hard feed straight away. I find that giving him one feed the first day and gradually working him on to it does not seem to affect them so much. Care should be taken not to over-heat a horse if it is at all subject to sand."

**CARE OF HORSES.**—Mr. N. Crawford read the following paper:—"Care of horses is a point of importance. Care should be taken in selecting a team of a good, active type of horse. To ensure a good, fast team one should breed young horses each year, and not break them in too young. A good stable, warm in the winter and cool in the summer, goes a long way towards keeping horses fit for work. I prefer a stable with a straw roof; it is warm in winter and cool in summer. After a long spell horses should be stable-fed, and not worked too long for the first week, and care should be given to the shoulders when breaking in a young horse. It is a good thing to wash the shoulders with cold water when you take off the collars. It will make the shoulders hard, and save a lot of trouble afterwards. Horses still hold their own, and a farmer should give attention to his brood mares. They should have plenty of green feed, both before and after foaling. When weaning foals they should have plenty of feed."

**MANAGEMENT AND CARE OF THE HORSE.**—Mr. E. Oswald read the following paper:—"The horse, we should at all times acknowledge, has intelligence, and will respond to good treatment. His only return for all the work that he does for us is his food and grooming, and occasionally extra care when he is sick or injured. Surely, then, all fair-minded men who are responsible for his care will be sufficiently good sportsmen to give him his just due. Unfortunately, with the hard times farmers are experiencing, the horse's fare is below standard in most cases, and we cannot therefore expect such a big day's work as would be the case in normal times. Illness in horses in this district

is mostly the result of sand, and the movement of that out of the horse in most cases results in its health returning to normal. I have used a mixture of half a pint of new milk and half a cup of honey as a drench, to which a dose of nux vomica was added, with good results. I particularly favor the horse having a few weeks' rest after seeding out on good green feed, with one feed of cocky chaff or hay, when hay chaff is not available. This results in the movement of the sand in the majority of cases. As to the handling of horses, I treat them kindly and firmly. Occasionally a horse is encountered that has bad and vicious habits. These are either the result of heredity or through mishandling during 'breaking-in.' If the result of heredity, little improvement can be expected, but faulty handling in its earlier life may often be corrected if one is prepared to spend time and patience in finding out the horse's viewpoint which he formed in his earlier life, and educating (or rather 're-educating') him. To be a success at handling horses, as of men, one needs to be a psychologist. I have a personal dislike to using the whip on horses, and usually manage to get a fair amount of work done without its use. As is good advice with the tractor, so with the horse team: Under-loading is preferable to over-loading."

#### YADNARIE (Average annual rainfall, 14.09in.).

Mr. W. Brown presided over an attendance of 12 members at the meeting held on June 10th. Officers were elected for the ensuing year.

#### YEELANA (Average annual rainfall, 16.12in.).

Meeting held March 12th. Present: 16 members. Mr. H. Adams (District Agricultural Instructor) gave an address, "Crop Rotation."

Meeting held April 9th. Present: 25 members. Mr. A. Ferguson, of the Moonta Branch, read a paper, "The Skim Plough."

Thirty members and visitors attended the meeting held on May 22nd, when addresses were delivered by Messrs. E. L. Orchard and H. D. Adams, of the Department of Agriculture.

### EASTERN DISTRICT.

#### (EAST OF MOUNT LOFTY RANGES.)

##### BOOLGUN.

Meeting held June 12th. Present: 21 members and seven visitors. Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Fallowing and Cultivation Methods," after which a lengthy discussion followed.

##### BUGLE.

June 10th.—Present: 15 members.

CARE OF STOCK AND NEED FOR A VETERINARY SURGEON.—Mr. B. Rohrlach read the following paper:—"Stock need a lot of attention in this district, and particularly horses. We have the usual trouble with sand, paddy melons, &c. Most farmers have their own special remedies for these complaints, but in most cases the animals die. Usually not much notice is taken of an animal that has been ill for a day or so, and when it gradually gets worse it is too late to get a 'vet' from the city. If a local 'vet' was available much valuable stock could be saved. In this district, where the farms are large, the holdings are a long way from town, and it costs much money for car hire to get a 'vet' out in addition to paying for his service. I suggest that the Loxton, Parunga, and Paruna councils, and perhaps Waikerie and Berri, engage a qualified 'vet' between them, and if he resided centrally to each of these places he could serve them all. As regards his salary, if all ratepayers paid in addition to their council rates, the services of the 'vet' would be free of charge, charging only for mileage of the car."

##### COPEVILLE.

May 21st.

The meeting took the form of a debate, "Combines *versus* Cultivator and Drill." Messrs. A. P. Hein, L. Carlisle, and G. H. Sutherland supported the combine, and Messrs. D. Neely, W. Johns, and C. Beckman spoke in favor of the cultivator and drill.

##### COPEVILLE.

Mr. C. F. Anderson (Acting Poultry Expert) addressed the meeting. A large number of members and visitors attended. The meeting concluded with a social and dance.

##### KALYAN.

There were ten members present at the meeting held on June 18th, when a paper, "Fertilisers," was read by Mr. V. Luhrs. It was decided to hold meetings alternately at Kalyan and Perponda.

## KANNI.

The meeting held on May 10th was attended by 10 members and five visitors, and took the form of a Question Box, when various subjects were introduced for discussion.

## KANNI.

Meeting held May 22nd. Present: 13 members and six visitors. Addresses were delivered by Messrs. W. C. Johnston and R. L. Griffiths, of the Department of Agriculture.

## KULKAWIRRA.

May 13th.—Present: 15 members.

The meeting took the form of a "Question Box." In answer to a question as to whether heavy super on new land caused it to dry out, Mr. Elliot stated that it caused too much growth, with the result that when warm weather came there was insufficient moisture in the soil. As to the most profitable breed of sheep for the district, Mr. Coombs considered that the Corriedale ewe crossed with a Dorset Horn ram was best for producing lambs for market. Mr. Fitzgerald favored pure Merino, because the wool was more saleable than crossbred, and crossbreds were such bad fencers. Where crossbreds were wanted, he favored the Shropshire cross. Mr. Elliot instanced Corriedale lambs at five months weighing 50lbs. Corriedales lived and fattened where Merinos barely held their own, were better mothers, and had better lambs. He did not like the Dorset or Shropshire, because the wool was inferior. In answer to an inquiry for the best method of dealing with two-year old shoots to get the best crop results, Mr. Oakley advised disc ploughing twice and cropping. The question whether it would be profitable to grow lucerne in the mallee was brought forward. Members expressed doubt on account of the dryness of the country during the growing period. Some members stated that the plants lived for years, and appeared again whenever good rains fell.

## KULKAWIRRA.

Mr. Coombs presided over an attendance of 15 members. The Annual Report was presented, and officers elected for the forthcoming year.

## LAMEROO (Average annual rainfall, 16.33in.).

Eighteen members and two visitors attended the meeting held on June 28th. An instructive paper, "The Farm Water Supply," was contributed by Mr. J. Kakeschke.

## MERIBAH (Average annual rainfall, 11.70in.).

Eleven members and four visitors attended the Annual Meeting, which was held on June 28th. After the election of officers, the meeting took the form of a social and dance.

## MILLENDILLA (Average annual rainfall, 13in.).

June 2nd.—Present: 10 members.

**WILD OATS.**—"Which is the best way to work fallow which is covered in wild oats, shallow or deep?" Mr. V. Eichler, who put the question, said that it had been his experience that working shallow, especially before seeding, was better. Last season he had worked one piece with heavy (scarifier) harrows and the other with light harrows, and that worked with light harrows was practically free from oats, whilst the other was badly infested. Mr. F. Barmann supported, and said that he had the same experience. Mr. V. Wegener said his land had wild oats coming through just before seeding, and in order to destroy them had put the cultivator through the oats about 4in. or 5in. deep; the crop turned out a failure on account of takeall, and where there was no takeall the oats smothered the rest of the crop. He also pointed out that wild oat seed lay dormant in large clods of earth, and towards seeding, when the land was usually worked to a fine tilth and weather conditions were suitable, the seed germinated. Never should a consolidated seedbed be sacrificed to destroy wild oats, as they had the ability to come through up to 5in. of soil, and it was useless to try and root them out. Mr. J. Buckley thought wild oats could be fed off by turning a flock of ewes and lambs on them. "Which is the best way to eradicate marshmallow on fallow?" Mr. J. Buckley said the only effective method was to cut them out with a hoe or pull them by hand; no implement was effective in cutting them off on account of their tough roots. "How long is the grain of wheat safe when there is a little moisture in the ground?" It was stated that wheat would germinate three times, provided the shoot or young plant did not grow to any length; it died back, and the grain became covered with mould, thereby retaining sufficient germinating power to germinate again when sufficient moisture was present. It was decided to arrange a "permanent" question box into which queries could be put, and which would be answered at the next meeting. Mr. C. Zadow offered to have a question box made and placed in a convenient position.

**NUNKERI.**

An instructive paper, "Poultry on the Farm," was read by Mr. E. Harding at the meeting held on June 11th, which was attended by 14 members.

**PARILLA** (Average annual rainfall, 14.15in.).

Meeting held June 18th. Present: Mr. C. Niendorf (Chair) and 10 members. An instructive paper, "Economy on the Farm," was presented by Mr. H. Johnson.

Previous meeting held May 10th. Present: Seven members. Matters of local interest were discussed.

**PARILLA WELL WOMEN'S** (Average annual rainfall, 16in. to 17in.).

April 29th.—Present: nine members and six visitors.

The meeting was devoted to the election of officers, and four new members were proposed.

A further meeting was held on May 27th, and was attended by 15 members and 10 visitors. Mr. F. C. Richards (Assistant Secretary) addressed the meeting on the work of the Agricultural Bureau. At the close of the meeting, a social gathering was held in conjunction with the men's Branch.

**PARILLA WELL WOMEN'S** (Average annual rainfall, 14.94in.).

Meeting held June 24th. Present: 17 members. The following papers were read and discussed:—"Bread Making," Mrs. Blacksell; "Bun Making," Mrs. Beckman. Samples of bread and buns, made according to the recipes in the papers, were exhibited.

**PARRAKIE** (Average annual rainfall, 14.54in.).

Mr. W. Halliday presided over an attendance of 22 members and 12 visitors at the meeting held on March 20th, when Mr. R. L. Griffiths (District Agricultural Instructor) gave an address, "Grading and Pickling Seed Wheat."

A further meeting, attended by 18 members and six visitors, was held on May 2nd. Mr. R. Wilson read a paper, "The Type of Cow for Dairy Purposes."

## PARUNA.

May 6th.—Present: 21 members.

Mr. R. L. Griffiths (Instructor for Murray Lands District) delivered an address, "Diseases of Wheat." Ball smut, he said, could be controlled quite effectively provided the farmer pickled the wheat properly. The cause of smut was neglect to sow good, clean seed and poor pickling. Mr. Griffiths pointed out that many machines of the grader and pickler combined were very uneven in the distribution of the dry pickle. He therefore urged the farmers to take particular care and see that every grain was properly pickled. Flag smut was becoming very noticeable throughout the district, and required careful handling, as it was a disease that very quickly spread. As a preventive he urged farmers not to graze the stubble on any account, but to burn it if possible. It had been proved that stock grazing on affected stubble would carry the disease to another part of the farm. Take-all, another disease, also required careful attention. The best method was bare fallow, then to grow a clean crop of oats, the seed to contain no wheat or barley. Two other diseases, whose life history was not known, but was being closely watched, were "No growth" and "Eel-worm."

## PARUNA, June 6th.

Present: Mr. A. C. Webb (Chairman) and 22 members. A special meeting was held to discuss the location of the experiments to be carried out on drifted sandhills. Messrs. A. Webb, F. Hondow, and F. R. Sumner were appointed to inspect land suitable on which to carry out the experiments. Mr. A. Petch suggested that each plot should contain a portion of undrifted soil; by doing so eight experiments would be carried out instead of four. A suitable piece of land was selected on Mr. F. A. Hondow's farm.

## CONFERENCE OF PINNABOO LINE WOMEN'S BRANCHES.

Twenty-seven ladies attended the special sessions held for women at the Conference of Pinnaroo Line Branches held at Lameroo on August 14th. Mrs. F. R. Koch (Wilkawatt) presided. The following papers were read:—"Laundry Work," Mrs. Oram (Wilkawatt); "Butter-making," Mrs. Phillis (Parilla); "Domestic Art in the Home," Mrs. Fewings (Pinnaroo); "The Sensible Kitchen," Mrs. Billing (Wilkawatt); "Cold Meat Dishes," Mrs. Mattischke. In addition to the interesting discussions that followed the reading of each paper, the following recipes and household hints were given:—To keep weedy flavors out of butter, add a few grains of saltpetre to the cream and stir twice a day.

**POTTED BUTTER.**—One pound loaf sugar, 1lb. saltpetre, 2lbs. of salt. Wash butter well and get all buttermilk from it. Crush sugar, saltpetre, and salt, and mix together. Add 1oz. of this mixture to every pound of butter (see that all small lumps of saltpetre have melted). Press into an earthenware jar, sprinkle salt on top to form a brine, and cover down. To make bread of a fine texture, delegates were advised to use less yeast and try adding some mashed potatoes to the bread whilst mixing it.

**CANDIED PEEL.**—To make candied peel, let peel dry one day, then soak in fresh water with a little salt added for three days. Boil a syrup consisting of two cups of sugar to one cup of water, pour on the strained pieces of peel, and allow it to stand until next day. Reheat the syrup to boiling point, again pour over the peel. Repeat three times and stand on a tray to dry with a little syrup in each peel.

**LAUNDRY WORK (DRESS SHIRTS AND COLLARS),** by Mrs. Oram (Wilkawatt).—Care must be taken to wash and boil out all previous starch from garments to be ironed. When starching collars, all should be put into the bowl at one time, so that the starch will be at the same consistency for them all. They should be rubbed well with the hands, wrung out, rubbed with a clean cloth, and rolled up in a clean towel for one hour. For shirt fronts, the starch needs to be very thin, and this thoroughly rubbed in. For ironing, a good, hot iron is necessary, but care must be taken not to have it scorching, as the collar must be rubbed with the iron until it is dry. When this special ironing has to be done, it is advisable not to try to do it the same day as the other ironing is done, because one must not be in a hurry to get it finished.

To treat a collar that persists in "blistering," it was recommended that all starch be washed out of the collar, dried, and then immersed three times in starch, wrapped up in a dry cloth for one hour, and then ironed in the usual way.

## PINNABOO WOMEN'S.

May 9th.—Present: 10 members.

**POULTRY.**—The meeting was held at Mrs. Nickolls' homestead, and the following paper was read by Mrs. Nickolls:—"To make a success of this sideline, stock should be bought from a reliable breeder. Now that the large size birds have proved themselves as good layers they can be reared for eggs and table purposes too. Birds should be housed properly and fed regularly. Poultry houses should face the north-east, which will permit of enough sunlight for the birds. Fowls require plenty of fresh air, but do not have a draughty fowlhouse. A concrete floor is good, and easy to keep clean. Petrol tins come in very useful for nests, water troughs, &c. A little clean sand is

# THE IMPLEMENT CO.

Offer a Complete Line of

## Harvesting Machinery

Don't risk a whole year's work when you can ensure against loss by getting light running, easily handled harvesting machinery on which you can always depend to harvest and market your crop. You will find in the Implement Co. line the finest materials and workmanship—and, what's best of all, years of satisfactory service.

**HORWOOD-BAGSHAW  
"GASTON" HEADER.**

The simplest, easiest running, and most effective Reaper Thresher in Australia. Sizes, 8ft. and 10ft. cut. This machine has fully earned its name—"The Better Built Header."

**HORWOOD-BAGSHAW  
"ILLMAN" STRIPPER.**

The Horwood-Bagshaw "Illman" Stripper is the result of many years close attention to the requirements of Mallee Farmers, and we are confident in offering this machine to fill the demands of the most exacting user. Made in 8-ft., 9-ft., and 10-ft. sizes.

~~~~~  
Write for catalogs and prices of the above, also "Horwood-Bagshaw" Winnowers, "Austral" Binders, "Horwood-Bagshaw" Wheat Elevators, "Frost & Wood" Hay Rakes and Hay Balers.
~~~~~

# THE IMPLEMENT COMPANY

**BANK AND BLYTH STREETS, ADELAIDE.**

good in one for a nest. Wheat is the best grain for egg production. Bran and pollard should be sound, and have a sweet, nutty smell. If sour, it may cause heavy losses. When using meat meal, 1lb. should be sufficient for 100 birds a day. Feed the meat meal in the hot mash in the morning in winter with chopped greenfeed. Give more greenfeed in the middle of the day. For the evening meal, feed wheat. Always see that the birds have plenty of fresh water kept in the shade. Shell grit is good to give the birds to peck at occasionally. Barley, oats, and rye are good winter fodders, also mustard and kale are recommended. Old crank case oil with kerosine is good for painting the perches for destroying tick in woodwork. This will also keep the fowls free from scaly leg mite. The scale is unsightly, causes lameness, and stops the hens from laying. Do not feed too much fruit in the fruit season. A little does no harm."

#### PINNAROO WOMEN'S.

June 6th.—Present: 11 members and two visitors.

Mrs. Fewings gave a demonstration of dressing poultry. She showed how to dress a fowl correctly for show purposes; how to bone a turkey; and how to stuff or season poultry, as well as other matters connected with poultry dressing.

#### RAMCO.

Mr. J. Boehm presided over an attendance of eight members at the meeting held on June 9th. Matters relating to the feeding of dairy cows on an irrigated fruit block formed the subject for discussion.

#### WILKAWATT WOMEN'S (Average annual rainfall, 16in. to 17in.).

Meeting held May 20th. Present: Seven members and one visitor. Mrs. W. Nevill, sen., read a number of household recipes, which were well discussed by the members present.

#### WILKAWATT WOMEN'S (Average annual rainfall, 16in. to 17in.).

Meeting held June 17th. Present: Eight members and one visitor. Mrs. A. Walsh read a paper, "Food Values," and supplied several useful recipes. Afternoon tea was served by the ladies.

#### YURGO.

The meeting of July 4th was attended by eight members, when an interesting paper, "Horses v. Tractor in the Mallo Districts," was presented by Mr. G. Tregilgas.

### SOUTH AND HILLS DISTRICT.

#### CHERRY GARDENS (Average annual rainfall, 35.03in.).

Members met at the residence of Mr. C. Terrell for the meeting held on July 5th. An interesting feature of the inspection of the property was the eradication of blackberries, which by constant ploughing, grubbing, &c., had been brought under control. Sown on land that was previously overgrown with blackberries, Mr. Terrell had successfully established an excellent plot of Subterranean clover. Afternoon tea was provided by Mrs. Terrell.

#### INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

Thirteen members attended the meeting held on June 17th, when an instructive paper, "The Cow on the Farm," was presented by Mr. Roads.

#### KANGARILLA.

June 13th.—Present: 14 members and visitors.

FARM EQUIPMENT.—Mr. L. Tune read the following paper:—"After several years' experience on farms in various districts, I have come to the conclusion that farmers work under difficulties. Many have few or no stock of bolts, nuts, &c., and a very poor assortment of tools. I have been told by employers that to have a good assortment of nuts, bolts, &c., and tools would cost much money, but this is not so. Most farmers visit a township or the city reasonably often, and for a few shillings spent each time it is surprising how quickly one can accumulate a stock of tools and other necessities. A few horseshoe nail boxes with cotton reels screwed in one end and fitted nicely in a big box make excellent drawers. The shed can be put in order when there is no field work to be done."

#### KANGARILLA WOMEN'S.

Meeting held June 19th. Present: Nine members and three visitors. The meeting took the form of a Question Box. Several questions were submitted for discussion.

**LENSWOOD AND FOREST RANGE** (Average annual rainfall, 35in. to 36in.).

On the occasion of the Annual Meeting, the Hon. Secretary (Mr. B. Lawrence) presented the Annual Report and balance-sheet, and officers were elected for the ensuing year. Other items, including "Codlin Moth Control," Pruning Apple Trees," etc., were discussed. Eleven members and visitors attended.

**MOUNT COMPASS.**

Meeting held May 1st. Mr. A. Kidman presided over an attendance of 35 members and several visitors. Mr. C. Verco gave an instructive address, "Stock Diseases in the Southern Districts."

**MOUNT PLEASANT** (Average annual rainfall, 27.46in.).

"Rural Competitions" was the subject of a paper delivered by Mr. Vigor at the meeting of the Branch held on May 9th, which was attended by eight members.

**RAPID BAY.**

June 12th.—Present: 17 members and three visitors.

**CARE OF THE BREEDING EWE AND TAILING THE LAMB.**—Mr. H. Hamlyn read the following paper:—"When financial difficulties confront the producer, more systematic methods and precautions should be taken of the flock. Adverse seasons have made sheep breeding more difficult in the past few years. This has been due to want of better management. Breeding ewes should receive first consideration. The flock should be mouthed, and faulty and weedy constitutioned ewes culled out for rations. This operation may be done soon after shearing and after the lamb has been weaned. Rams should be put with the ewes not later than the end of November, thus procuring an early lamb which will be well grown in spring when feed is good. After the rams have been mated, the flock should be frequently yarded or mustered into a small paddock for the first five or six weeks, to assure a better percentage and a more even lambing. During the mating season, the flock should be allowed to graze on good pastures. A month or five weeks prior to lambing, the ewes must be crutched and all rams removed. The wool should be clipped as short as possible; this gives the lamb a better chance to find the teats, and also minimises ravages of the blowfly. Every care should be exercised whilst crutching, in order not to handle the ewe roughly, otherwise losses may be expected. When lambing commences, the paddocks should be looked around once a day, to pick up any ewes that may be down or need attention. All dogs must be kept from the lambing paddock. A good plan, where possible, is to have the flock in several small paddocks for a few weeks, and as time goes on the ewes with the stronger lambs can be worked out into the larger paddocks. A little time spent in this direction is well worth while, more especially on a small holding. Changing the ewes from one paddock to another or on to any fresh picking will give them more milk, and so enable them to rear a better lamb. On no account should a ewe with a young lamb at foot be placed on dry feed. If droughty conditions prevail and hand feeding has to be adopted, some nutritious or milk producing ingredient must be given with the feed, otherwise the lamb might just as well be sacrificed to save the life of the mother. Before tailing operations commence, all yards should be cleaned out and refuse carted away to prevent disease. If a knife is used for tailing, it should be well-sharpened and sterilised before using. I prefer the searing iron; it is always sterilised in the fire bucket, and gives better results in many different ways. A day of moderate temperature should be chosen for tailing—not too hot or too cold—and sufficient hands should be available to enable the operation to be finished by 3 o'clock in the afternoon. This gives the ewe when turned out time to get a feed and mother her lamb before darkness sets in. Next, an inspection should be made of the flock to see that everything is in order. The flock should be left to settle down for a day or two before shifting or driving any great distance." In the discussion that followed, some members thought the knife was the best instrument for tailing. They considered that this method did not take so much out of the lamb. Mr. Hamlyn thought it took the lamb longer to get over the operation when the knife was used. He pointed out as an instance where one was rearing pet lambs and feeding them with the bottle, that the lamb tailed with the searing iron would take milk immediately after the operation, but the lamb tailed with the knife would often go several days before taking food. The writer of the paper considered that in cases where lambs were being bred for market, those tailed with the iron were ready for market a fortnight before those that were done with the knife.

**ROCKWOOD.**

Mr. C. Hodgson presided over an attendance of 10 members and two visitors at the meeting held on June 20th. Mr. F. Mudge read a paper, "Preparation of the Seedbed and the Treatment of Takeall." Officers were elected for the ensuing year.

# CROWN LANDS.

---

Lands in the Hundreds as shown below are open to application until 3 p.m. on Tuesday, 7th October, 1930.

Lands in the Hundreds of APOINGA, BAROSSA, CAROLINE, COTTON, EBA, ENCOUNTER BAY, GAMBIER, HOLDER, HOOPER, KINGSFORD, KONGORONG, MAYURRA, MONARTO, PARCOOLA, PEEBINGA, PRICE, REDHILL, RIDLEY, TICKERA, VINCENT, WAITPINGA, and WARRENBEN.

Full particulars are published in the *Government Gazette*, and plans and detail may be obtained on application to the Secretary for Lands, Box 293A, Adelaide.

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Secretary for Lands, Box 293A, Adelaide.

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

# AGRICULTURAL PUBLICATIONS.

The following publications have been issued and are available for distribution at prices mentioned:—

"First Aid to the Horse," by F. E. Place, B.V.Sc., M.R.C.V.S., &c.; price, 3s.; posted, 3s. 2d.

Journal of the Department of Agriculture, 5s. per annum in advance; 1s. per single copy to residents in South Australia. Other places, 10s. per annum; single copies, 2s. each.

The bulletins and leaflets may be obtained by sending a 1d. stamp for postage.

All communications must be addressed—Editor, "Journal of Agriculture," Box 901E, G.P.O., Adelaide.

THE AGRICULTURAL BUREAU.—Particulars of this Organization, of which every farmer should be a member, can be had on application to the Department.

# LIBERAL FEEDING— AND ITS RESULTS!

Under the heading "GREATER VIGOR AND BETTER FRUIT," the *Sydney Daily Telegraph*, of the 17th April last, called attention to the excellent results attending the use of

## SULPHATE OF AMMONIA

on an apple orchard in the Blackheath district of N.S.W.

The outstanding feature of the results so far is the increase in the tree growth and improvement in the colour of the foliage of the sections which have had nitrogenous fertilisers. Mature trees that had dressings of 4lbs. of Sulphate of Ammonia in August, and a similar amount in January, stand out from all others.

## AGRICULTURAL VIEWS AND COMMENTS.

### Conferences.

Conferences of the Agricultural Bureau will be held as under:—

Non-irrigated Fruits Districts, November 4th, at Angaston (Secretary, Mr. K. Robinson).

Papers, questions, &c., for Conferences should be in the hands of the General Secretary, Agricultural Bureau, Adelaide, a fortnight before the above date.

### List of Probable Dates of Country Shows During 1930.

| Name.                              | Secretary.        | Address.           | Approx. Date of Show. |
|------------------------------------|-------------------|--------------------|-----------------------|
| Central Yorke Penin.<br>(Minlaton) | D. M. S. Davies   | Minlaton . . . .   | October 22nd          |
| Mount Gambier . . . .              | H. L. Kennedy .   | Mount Gambier . .  | October 22nd and 23rd |
| Tatiara (Bordertown)               | A. F. Baker . . . | Bordertown . . . . | October 29th and 30th |

*Secretaries of Show Societies are invited to advise the Editor of the dates of their Shows.*

### Fodder Crops for the South.

The following information is supplied by Mr. W. J. Spafford (Deputy Director of Agriculture) in answer to a request from the Langhorne's Creek Branch of the Agricultural Bureau:—

#### SUDAN GRASS.

Sudan grass is an annual sorghum which differs from the well-known forage sorghums in that the plants produce a lot of relatively fine stems rather than a few coarse ones. It is a summer-growing crop, and as such the seed should not be sown until the soil has warmed up in the spring, say, in September. Best crops are secured if sown in rows spaced about 2ft. to 3ft. apart, and the land between the rows kept loose and free from weeds by cultivation, but in good, rich locations the seed can be broadcasted or be drilled through every hoe of the ordinary seed drill. From 7lbs. to 10lbs. of seed per acre should be used, according to the method of seeding, and at the time of seeding at least 1cwt. superphosphate (45 per cent.) should be used. Sudan grass produces good, green forage, and can also be converted into a rather coarse, but palatable and nutritious hay.

#### RAPE.

Rape is also a summer-growing crop, and should be sown in spring, but as it will germinate when the soil is still fairly cold, and will grow in cooler conditions than will most other summer forages, it can be seeded in August in all but the very heavy rainfall districts of the State. Rape is a good crop on which to wean lambs or to fatten sheep, but when grown alone tends to scour all animals fed on it, and as a consequence it is usual to sow a little mustard with it. A mixture of 4lbs. rape, 1lb. mustard, and 1cwt. superphosphate can be drilled in with the ordinary seed drill, remembering that the seed should not be mixed with the superphosphate for more than four hours before it is to be drilled into the land. When livestock are feeding off the rape they should be gradually made accustomed to it, when it will be found to be a really good forage, particularly for sheep.

#### MANGELS.

The mangel crop is an expensive one to grow, because it needs the same treatment as do market garden crops, in that the land must be kept well cultivated and free from weeds, and the plants must be widely and evenly spaced in the rows. It is seeded in

# THE WORLD'S Easiest-Running Cream Separator ... because it runs on Ball Bearings

Every high speed point has high-grade ball bearings in the McCormick-Deering Cream Separator. It takes much of the work out of the morning-and-evening separating. No wonder it makes a hit with every man and woman who sees and turns it. And that's only the start.

Here's the  
secret!

It's the combination of high-grade ball bearings (at the vital points 1, 2, 3 and 4) and positive, automatic lubrication, that makes the McCormick-Deering so easy to turn.

The McCormick-Deering has many other points of improvement. It is setting new records in clean skimming. It is easy to wash, and it is self-oiling. Visit the McCormick-Deering agent and see something really modern in cream separators. Six sizes — hand, belted or electric — for one cow or a hundred.

# McCORMICK- DEERING

the spring with a drill, in rows about 30in. apart, using from 6lbs. to 10lbs. of seed per acre. After germination the rows are carefully thinned out by hand, and from then onwards the land is constantly cultivated, and all weeds are removed. The crop is a heavy feeder, and so should be well manured, and, if possible, 20 tons or more of farm-yard manure should be spread per acre before ploughing, and then 3cwts. to 4cwts. of superphosphate and 1cwt. to 1½cwts. sulphate of ammonia should be applied as well. Enormous yields of mangels can be obtained in suitable locations, and it makes an excellent winter feed for dairy cows. In the late autumn the roots should be lifted, trimmed and stacked in clamps, and protected with straw and soil, so that they will properly mature for winter feeding. If the roots are to be fed to livestock soon after being lifted they should always be left lying on the surface for some days to properly wilt, or else they should be sliced and a small quantity fed in admixture with chaff and other foodstuffs. If fed whilst still in the ground or as soon as lifted, trouble is being courted, as in some conditions they prove fatal to livestock, particularly to dairy cows.

#### WIMMERA RYE GRASS.

Wimmera rye grass grows well in this State wherever barley grass flourishes, and it replaces this latter grass with advantage, because it is more nutritious, more palatable, and has no stage when it is objectionable to farm stock. It is easily established by drilling in a couple of pounds of seed per acre with a cereal crop which is to be harvested for grain. The seed is collected with the harvester, and being light is blown out of the tail of the machine, and is distributed all over the field. If a pure stand is required, 10lbs. to 15lbs. seed should be drilled to the acre into prepared land with at least 1cwt. superphosphate, and this should be done in the autumn or early winter. Wimmera rye grass is an annual, but it behaves like other weeds, and seeds itself with such surety that once established it will always be present. Livestock do well on this grass, and in the good years it grows like a cereal crop and makes first-class hay.

---

#### Flax Culture.

Mr. W. J. Spafford (Deputy Director of Agriculture) has supplied the following information relating to flax culture to the Tantanoola Branch of the Agricultural Bureau:—Flax can be grown in most well-drained fertile soils in districts where the average rainfall exceeds 22in. per annum, and particularly so in such districts if the soils are of a type which produce good cereal crops. It should be seeded in April, and can be broadcasted or be drilled from the wheat cups of the ordinary seed drill. If the crop is to be grown for linseed only, about 30lbs. of seed per acre is sufficient, but if for flax and linseed then from 60lbs. to 65lbs. of seed is necessary. Manuring should be something the same as for cereals, but best results are secured if the land is in such good heart that only light manuring is necessary. During the growing period of the crop all tall-growing weeds should be pulled by hand. The crop is harvested with a binder when the bolls have turned a golden brown color, and if the fibre is to be saved, the heads are passed through rollers which liberates the seed, then the stalks must be retted, either in water which takes about 20 days or by spreading it on grass and turning it a couple of times, when the dew will lead to complete retting in five or six weeks. If grown for seed only, the crop is cut with binder and the seed removed with a header, or it is harvested in the field, as are cereal crops, with a reaper-thresher. The straw that remains is used as a foodstuff for farm animals or for anything that the cereal straws are useful for. A seed crop should yield somewhere about 20bush. per acre, which at present is worth somewhere around £15 per ton. We have no means of knowing what fibre is worth at present as it is not produced in this State, and, as a matter of fact, there is very little produced anywhere in Australia.

# FULL POWER WITH EVERY SPARK

To operate your tractor at a normal working speed of 1,000 revolutions per minute, with 250 sparks at each plug point in the same period, and the explosion temperature in each combustion chamber reaching 2,500° F., you must employ a fuel with intense vaporization and utmost power qualities, and an oil that resists the terrific heat by providing an unbroken film of lubrication on every working surface.

Cross Power Kerosene and Golden Shell Oil will meet these conditions—unfailingly—whether for a few minutes through heavy soil or for a whole day's solid plowing.

Tractor owners everywhere have proved this. Test these products for yourself.

# CROSS POWER KEROSENE and GOLDEN SHELL OIL

**Barley for Grazing.**

Replying to the question, "Which is the best crop to grow for grazing in the Mallee—wheat, oats, or barley?" which was submitted by the Boolgun Branch of the Agricultural Bureau, Mr. W. J. Spafford says mixtures of two or more cereals produce more green forage than if the different kinds are sown separately, and in all probability for most Mallee districts in this State, it will be found that a mixture of 30lbs. oats and 30lbs. rye per acre will provide more grazing than any other mixture. If no rye is available, a mixture of 50lbs. barley and 30lbs. oats per acre will be quite suitable; but it may be better to use a mixture comprised of 30lbs. barley, 30lbs. oats, and 20lbs. wheat. If full grazing results are to be secured, plenty of seed must be used, because the competition of closely packed plants forces all plants to grow quickly, and so much more feed is provided when it is most needed, *i.e.*, in the winter. Early seeding is also essential if winter feed is to be secured. If a single cereal is to be grown, oats sown early is preferred to the other cereals. Of the barley varieties commonly grown in South Australia, either Roseworthy Oregon or Shorthed will prove superior to others for the Mallee districts.

**Popular Wheat Varieties.**

"A list of the most popular wheats in this State, showing whether early, late, or otherwise." This question was asked by the Miltafie Branch of the Agricultural Bureau. Reply:—The twenty (20) most popular wheats are:—Gluyas (very early), Late Gluyas (early), Ford (mid-season), Federation (mid-season), Currawa (mid-season), Sultan (early), Nabawa (early), Caliph (early mid-season), Daphne (early), Joffre (mid-season), German Wonder (mid-season), Florence (early), Major (late mid-season), Felix (early), Canberra (very early), Queen Fan (mid-season), Gallipoli (mid-season), Silver Bart (early mid-season), King's White (very early), Yandilla King (late mid-season).

**Pickled Barley for Livestock.**

"Would it be safe to crush and feed to stock barley that has been pickled with formalin at the rate of 1½ eggeups to 4galls. of water per 3 bags of barley?" This query was received from a subscriber to the *Journal of Agriculture*. Reply:—The small amount of formalin present on the barley pickled by your method would not injure livestock in any way, even if fed to them soon after having been pickled, and the danger becomes less and less with time. Formalin is a solution of a gas (formaldehyde) in water, and as the pickled wheat dries much of this gas is liberated into the air, and as time goes on all of the formaldehyde is eventually given off, so that some little time after being pickled and dried there is not much formalin left to affect the grain in any way.

**Fodders for Dairy Cows.**

A correspondent at Loveday (River Murray) sought information as to (1) what crops could be grown under irrigation conditions to replace bran or concentrates for feeding to cows, (2) the value of crushed sunflower seed compared with bran, and (3) the feeding value of crushed maize. These queries were submitted to the Chief Dairy Instructor (Mr. H. B. Barlow), who says (1) lucerne is in many respects a complete food and will give excellent results without the addition of any concentrates. Such things as pumpkins, turnips, mangolds, &c., if cut up and fed with lucerne chaff, will give good results. (2) Crushed sunflower seed has a higher feeding value than bran, and is comparable to linseed meal. Bran has an added advantage for feeding dairy cows, since with dry feed it has a laxative effect and is very palatable. (3) Crushed maize is an excellent concentrate for dairy cows, and should give quite as good results as bran or oats.

**Barley for Hay.**

Mr. R. C. Scott (Supervisor of Experimental Work) has tendered the following information to the Elbow Hill Branch of the Agricultural Bureau:—On account of the fact that barley dries out to a very light weight on cutting for hay, it is not generally utilised for this purpose. However, weight for weight it makes a good quality foodstuff comparatively with wheaten hay. The time to cut is the same as that for wheat, namely, when the grain has reached the soft dough stage, and it is better to err on the green side than to allow the crop to become over-ripe. The following is the average of analyses of wheaten and barley hay, the latter being quoted by Henry in his "Feeds and Feeding":—

|                         | Wheat.       |                          | Barley.      |                          |
|-------------------------|--------------|--------------------------|--------------|--------------------------|
|                         | Composition. | Digestible Constituents. | Composition. | Digestible Constituents. |
|                         | %            | %                        | %            | %                        |
| Moisture . . . . .      | 10.0         | —                        | 15.0         | —                        |
| Ash . . . . .           | 6.2          | —                        | 4.2          | —                        |
| Protein . . . . .       | 5.1          | 2.8                      | 8.8          | 5.7                      |
| Fibre . . . . .         | 24.4         | 7.9                      | 24.7         | 15.3                     |
| Carbohydrates . . . . . | 53.5         | 33.7                     | 44.9         | 28.3                     |
| Fat . . . . .           | 0.8          | 0.5                      | 2.4          | 1.0                      |

The figures for barley were obtained from samples cut in the milk stage and indicate a higher percentage of digestible protein, fibre, and fat, and a lower percentage of digestible carbohydrates than wheaten hay. It is customary to compare foodstuffs by what is termed the "starch equivalent," and by calculation this is found to be 30.9 per cent. for wheaten hay and 36.5 per cent. for barley hay. Therefore, from this point of view the latter fodder shows to advantage, but because of its bulky nature and low yield per acre the production of wheat hay is to be preferred.

**Treatment of Salt Patches of Land.**

Replying to the question, "What treatment do the Departmental Officers recommend as likely to bring back patches of magnesium or salty ground to a state of fertility?" which was submitted at the Conference of Upper North Branches of the Agricultural Bureau, Professor Perkins said this question was far more difficult to reply to in the North than in districts with a heavier and more regular rainfall. A similar question had been put to him by farmers on Yorke Peninsula, and he had had the satisfaction of learning a few years later that the treatment recommended had proved satisfactory. The solution of the difficulty depended primarily on the origin of the salt. "Where does it come from and why does it settle on a given spot whether a whole field is affected or only limited areas which show no signs of extending?" Essentially it should be remembered that salt, because of its ready solubility in water was extremely mobile in the soil, varying in its position from year to year and even from season to season in the same year, and because water tended to flow towards low spots and hollows, so normally salt which was carried in water tended to accumulate at those low spots and hollows. Generally speaking salt was more frequently encountered in arid and semi-arid districts than in localities of heavy rainfall because of the absence of a means of removing it by natural drainage; where rivers existed, rains that found their way into the rivers carried the salt to the sea, which was the great salt water reservoir of Nature. The sea returned it in the form of spray to coastal lands, and even penetrated the interior in time of gales. Disintegration of rocks also lead to the formation of salts. In this State salt did comparatively little harm to crops. Suppose, however, an abnormally wet year were experienced in an arid district. The heavy rains dissolved much of the salt scattered over the land; they drained towards the lower spots, evaporated, and left behind a dangerous accumulation of salt in the surface layers which would prove dangerous to vegetation. Here the salt remained unless removed, which could be done by under drainage if an outlet for drains could be found and if the rainfall were sufficiently heavy to reach the drains. But even in most circumstances the drainage

would be very costly, and not worth while except on land of very high value. To ensure some degree of success with this treatment it was necessary to understand how the salt acted. Owing to its solubility in water it was dissolved by Winter rains, and penetrated as deeply as the yearly rainfall penetrated. Hence, in Spring the salt was as deeply seated as at any time of the year. Throughout the Summer it rose to the surface with capillary water which was evaporated, and was left on the surface, and evaporation continued until late Autumn. Hence surface salt concentration was at its maximum towards the end of Autumn when farmers wanted to sow their seed. This condition of excessive concentration prevented all germination, and the land continued bare throughout the season and subject again to intense Summer evaporation. There were two points to be recalled if they wanted to minimise trouble:—(1) They must check evaporation and consequent salt concentration, and (2) sow at a time when the surface was comparatively free of salt.

To check evaporation the salt patches must be kept under vegetation of some kind or other. Heavy dressings of straw and stable manure would also help. In ordinary circumstances they could not hope to grow wheat on these salt patches with any chances of success, because crops must be seeded late in the season when rain had washed the salt into the depths of the subsoil beyond danger of damage to germinating seed and young plant roots.

The safest plan was to plough the salt patch late in Autumn on a good deep furrow in such a fashion as to invert the furrow slice completely. At this time of the year nine-tenths of the salt was concentrated in the first inch of soil at the end of a long, dry summer. If a 6in. furrow slice was completely inverted, it would place the salt layer 5in. below the surface, and early Winter rains penetrating the broken surface would carry it down deeper still. That would tend to sweeten the surface layers in which the seed germinated and young roots developed. Hence he had always recommended sowing not wheat but barley, not because it was more resistant to salt than wheat—which it was not—but because it could be sown with safety very much later, say, late in July. It would germinate, and by keeping the soil covered, prevent the rise of the salt under evaporation. If possible, old stable manure could be worked into the land prior to seeding.

If, owing to a lack of a sufficiency of Winter rains, barley failed, Sudan grass could be sown as soon as the soil was warm enough. If it germinated, it would cover the soil and check evaporation and provide feed. It should not be fed too close so as to maintain a cover of vegetation as long as possible. Bearing in mind that nine-tenths of the salt present was towards Autumn in the first inch of soil, the surface could be scraped off with a sharp scoop and removed if one had the means of doing so. Treatment such as he outlined had proved successful on Yorke Peninsula, but he could not guarantee it in the absence of a sufficiency of rain. Crops would absorb some salt and so reduce the quantity present. The main object, however, was to check concentration.

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

"W. Bros.," Coomandook, report light draught mare which is lame with a swelling above fetlock on back leg.

Reply—It can only be assumed that the swelling is on the back of the affected leg and affects the tendons and sheaths. Treatment: A hot antiphlogestive poultice should be applied to the affected part and covered with a bandage. Repeat daily for seven days. When heat and pain have disappeared, bandage fairly tightly for seven-ten days, removing and replacing bandages daily, then turn out for at least five months.

"E. H.," Moorlands, has aged gelding with swellings on the inside and outside of the knee and the offside front leg.

Reply—Clip hair over swelling and rub a blister of biniodide of mercury (1-8), which you will have to obtain from a chemist, into part for 10-15 minutes. Be careful not to rub into folds at back of knee. Tie horse up short so that it cannot lick part and next day wash off blister and rub in a little olive oil. Turn horse out for four-six weeks.

"H. McD. V.," Mount Pleasant, asks treatment for sucking lamb about three months old which developed stiffness in the neck, limbs, and jaws.

Reply—The symptoms described are typical of tetanus, commonly known as lockjaw. It is not stated whether the lamb was an orphan or had been "marked." The cause is a germ which as a rule gains entrance through a wound, and not infrequently follows docking of tail, &c. The treatment to adopt is to search carefully for wounds. When found, wash them with a disinfectant solution, remove the scabs, and apply strong lysol to the surface. As the symptoms develop only after damage has been done to the nerve endings (spinal), the mortality is heavy, and preventive measures such as follow are the best cure. When lamb-marking, see that all knives, &c., are sterilised by boiling and kept in a dish of strong disinfectant (lysol, two tablespoonfuls to the pint of water), also that the operation is carried out away from old sheep yards (the soil of which teems with the causal organism). After the operation is completed, the lamb should be released on clean ground and not placed in yards.

"A. L. V.," Brentwood, has heifer difficult to milk.

Reply—The condition described is probably associated with the first functioning of the mammary gland and due to congestion. The following treatment is advised:—Application of hot fomenta to the udder for 10 minutes at a time, with water kept at even temperature, but not hot enough to scald. Dry well and then massage the udder gently but firmly with camphorated oil. This treatment should be carried out twice a day before milking.

"C. B.," Riverton, reports gelding discharge from nose, offensive breath, heavy cough, and labored breathing.

Reply—The horse has possibly got pneumonia. Put in a warm airy shed and rug. Supply green feed and bran mashes. See that plenty of fresh drinking water is available. Have the following medicine made up:—Ext. belladonna liq., 4 drams; potassium chlorate, 4ozs.; powdered camphor, 1oz.; glycerine, 4ozs.; treacle, 8ozs. Give a tablespoonful on tongue three times daily.

"E. W.," Brimpton Lake, reports (1) cow with lump near the top of one teat; (2) death of pig. *Post-mortem* showed long worms in gut.

Reply—(1) The lump may be a sequel to mammitis or inflammation of the udder. Further, in certain families possessed of narrow supple teats, growths in the interior of the teat may develop during the first lactation period. Treatment is not satisfactory. As milking

is unaffected, I would not suggest interference. (2) These worms are known as "Ascaridae," and affect young pigs in particular. Weaning time is the most susceptible period. Affected pigs become listless, will not eat, cough frequently, and breathe with difficulty. There is a marked heaving of the flanks and breathing is increased (thumps, heaves). Less badly affected pigs do not eat well, rapidly lose condition, and become stunted. Frequent fits of coughing. Convulsive fits are uncommon. Various treatments can be recommended. The following is suggested (treat each affected pig separately):—(1) Starve for 24 hours; allow water only. (2) At the end of that time give santonin in a small feed of skim milk and pollard. The dose is as follows:—For a 15lb. pig, 2 grains; for a 30lb. pig, 3 grains; for a 45lb. pig, 4 grains; for a 60lb. pig, 5 grains; and so on up to a maximum dose of eight grains. Give medicine in the evening. (3) Next morning give Epsom salts (4ozs. for a pig of 100lbs). To administer, dissolve in warm milk (a quart of milk to each 4oz. of Epsom salts). Besides medicinal treatment, all manure should be burnt. This treatment will only get rid of worms in the pig, and will not prevent reinfestation, which occurs through pigs eating feed infested with the eggs. The following sanitary measures are recommended to deal with the infestation of the premises:—(1) If sties are old and insanitary and not of great value, it is suggested that the site be moved. (2) All pigsties should have floors which are impervious to moisture—concrete or brick. (3) Drainage should be supplied. (4) Open grazing in small paddocks of young pigs. (5) Regular cleaning of sties and disposal of manure.

"W. B. D.," Pinnaroo, has (1) mare in low condition, infested with lice, and cannot raise her head. (2) Mare in foal, off feed, and breathes quickly.

Replies—(1) The weakness and stiffness may be due to an ankylosis (or knitting) of the spine, in which case a recovery cannot be looked for. It may only be associated with the general debility, and the following course of treatment may be tried:—(1) To rid the animal of the parasites, which are most probably lice, clip all over first, if the coat is at all heavy, and burn the clippings. Choosing a bright sunny day, wash all over with warm soapy solution, with a teaspoonful of lysol added for each pint of water. Apply with an old grooming or scrubbing brush. Dry thoroughly. These washings should be repeated two or three times at intervals of a week to 10 days. (2) Have animal's teeth attended to if possible. Give internally to commence with a drench of raw linseed oil, 1½ pints; turpentine, four tablespoonfuls. Subsequently, supplement grazing by giving bran and chaff, and give one tablespoonful of Fowler's solution of arsenic in damped feed night and morning for a fortnight. The condition is probably due to the combined factors of work and advancing pregnancy. Probably the best thing would be to turn the mare out on suitable green feed till after foaling time.

"M. N.," Wauralte, reports death of cow due to milk fever, and asks for treatment for future cases.

Reply—The only treatment to apply is to pump up the udder tightly and tie teats with tape; remove after two hours. After inflation gently massage udder. Prop cow up on bricket and turn from side to side every three-four hours. If no improvement, repeat pumping every few hours until she rises. This treatment is usually successful, but not always so.

"W. H. P.," Sevenhills, reports lambs with swollen ears, nose, and mouth.

Reply—The symptoms described are similar to those shown by sheep which are grazing on trefoils or clovers, the disease being known as Trefoil dermatitis. It is due to the presence in such plants at certain periods of a substance which in conjunction with

strong sunlight causes a reaction on unpigmented skin, such as ears, face, and on the back. It is suggested that sheep be moved into another paddock, and that affected lambs be kept housed or in shade. Lamp black and oil may be applied to affected parts. It would be interesting to hear further particulars from you as to whether the pasture the sheep have been on is luxuriant in growth, also a description of the symptoms, such as whether there is redness, weeping, and if ears necrose.

"A. B. M.," Brinkley, asks cure for worms in pigs.

Reply—Starve the pigs for 18-24 hours. Then give the following dose:—Santonin, 5 grains; calomel, 5 grains, for a pig weighing 100lbs. (Increase or decrease the dose proportionately according to the weight of pig treated). The following day give 2ozs. to 3ozs. Epsom salts in thin slops. To prevent reinfestation, it will be necessary to thoroughly clean out the floors of sties and the feed and water troughs twice weekly.

"E. A. R.," Taruma, reports (1) cow with film over eye; (2) lice on pigs.

Replies—(1) Bathe the eye with lukewarm boracic lotion and instil a few drops of the following into the eye two or three times daily:—Zinc sulphate, 4 grains; boracic acid, 4 grains; distilled or boiled water, 2 tablespoonfuls. (2) Use the following preparation:—Hard soap,  $\frac{1}{2}$ lb.; kerosene,  $\frac{1}{2}$ gall.; water, 1gall. Dissolve the soap in the water first, then add the kerosene and mix well till it is all emulsified.

"E. H. W.," Kybybolite, asks treatment for cow with "itch."

Reply—The condition is due to lice, and is a common complaint during the winter and early spring months. Treatment: Procure from a chemist a quantity of sodium fluoride (1oz. per head of stock), and by means of a tin shaker apply it to the body and parts affected and then rub it in with the hands. Repeat if necessary in five days.

## ORCHARD NOTES FOR SOUTHERN DISTRICTS. OCTOBER, 1930.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

Orchard practice this month, with that of last month, will have a great influence on the quality of the fruit to be harvested, and probably on the quantity as well. If cultivation and preventive spraying have been carried out thoroughly we will have little to fear about the crop, given normal weather. But we must continue the work to get best results; soil surface must be kept loose and free from weeds, and the necessary sprays must be applied at the correct time.

For fungus diseases after the fruit has formed use lime sulphur sprays, or dry powders when the weather is such as demands this precaution; lime sulphur is preferred, because the copper mixtures have a tendency to russet the fruit. Vines require the finest sulphur mixture with a good blower if *Oidium* is to be checked. Aphides, thrips, and red spider must be stopped, or damage will result; black leaf 40, wet or dry, will give good return for the best efforts.

For codlin moth we have to rely on arsenate of lead, and we must have it on before the calyx closes, commencing when the majority of petals are falling. After the fruit has formed it is necessary to keep a coating of arsenate of lead during the growing period, or one or other of the white oils may be used, care being exercised not to spray on very bright days. The addition of black leaf 40 adds to the efficiency and makes it a dual purpose spray.

See that young trees (especially citrus) and vines do not suffer for want of water, and always loosen the soil about them after watering.

Strawberries may still need sulphuring if mildew shows; it should be applied only lightly, or it will cause considerable damage on a hot day.

Tomatoes require attention continuously, as disease runs through a plot so quickly; root out and burn all diseased plants; use only enough water to keep the soil moist; open up houses on very hot days, and close again at night.

Cincture vines as the caps start to fall from the blossoms; a narrow cut is all that is required, not more than 1/16th of an inch wide, and through the bark only.

Picking bags or boxes, trays, and other drying equipment should be clean and in repair ready for use.

## ENSILAGE MAKING.

The questions contained in the accompanying article were submitted by a correspondent at Watervale to Professor Arthur J. Perkins (Director of Agriculture), who has supplied the desired information.

1. *I have an old stone room with cellar beneath. This is 12ft. square, and by removing the floor I could get an approximate height of 15ft. Would this be a suitable place to use as a silo?*

It is preferable to have a circular silo because the corners of the square do not allow the whole material to slip down as evenly as in a round silo. The chief danger is that you will have air spaces in the corners on which the ensilage will go mouldy. I suggest that if you follow out your plan you round off the corners as much as possible. For a silo pit having, say, a diameter of 12ft., the proper height would be 24ft., so that the height you have available—15ft.—is rather low. You can, however, overcome this difficulty by heavily weighting the silo when you fill it up.

2. *In wet winters the cellar is very damp; in fact, water has accumulated at times. Would this be detrimental?*

The result of having water seeping into your silo will probably lead to the loss of some of the ensilage at the bottom of the pit. I understand that the cellar has not been faced, and suggest that you cement it before you use it as a silo, particularly as the smooth surface is essential to the gradual settling of the ensilage.

3. *What is the correct temperature?*

4. *How is the temperature controlled?*

5. *Is it necessary or advisable to use a thermometer, and if so, where can such be obtained?*

I do not think it is necessary to worry about a thermometer to follow out the rise in temperature. The rise in temperature will follow normally, and the rise will be quite sufficient in the 12 hours' interval which will take place between each working day. The thing to do is to avoid too high a rise in temperature, which is wasteful of the material, and the way to get over that is to fill as rapidly as possible and to have no interval in the way of filling. If by some mischance you are obliged to stop before you have filled your pit, level it out as carefully as you can, tramp it down and weight it, and then remove the weights and start again.

6. *What is the correct stage to cut cereals for silage?*

The correct stage would be, say, from 10 days to a fortnight after the anthers of the flowers show outside the head of wheat, or probably—according to districts and seasons—from a fortnight to three weeks before hay time.

7. *Would it be advisable to bind cereals with a view to it packing closer, and also, for convenience in handling?*

Whilst you can fill the pit with long ensilage, preferably in bound sheaves, the most effective method, and the one which will enable you to store the maximum in the pit, would be to chaff it straight out of the field into the pit. Do not cut the bands, because you will be enabled to empty the pit far more readily in the sheaves than you would with long, tangled hay.

8. *Could a layer of artichokes be put in now and then, or would the bitterness affect the whole mass?*

Although I have no personal experience of the matter I believe that the artichoke will make very fair ensilage, particularly if mixed with cereals.

9. *What quantity of silage constitutes a fair ration for a milking cow?*

The following is a ration for dairy cattle, according to the milk supplied, and per 1,000lbs. live weight:—

|                           | Per Day—        |                 |                 |                 |
|---------------------------|-----------------|-----------------|-----------------|-----------------|
|                           | 10lbs.<br>Milk. | 20lbs.<br>Milk. | 30lbs.<br>Milk. | 40lbs.<br>Milk. |
| Cereal ensilage . . . . . | 42              | 42              | 45              | 45              |
| Wheat-hay-chaff . . . . . | 10              | 10              | 10              | 6               |
| Bran . . . . .            | 3½              | 10              | 15              | 20              |

If you feed ensilage alone, 60lbs. to 80lbs. of ensilage per day.

10. *The comparative weights of silage and hay?*

If you make ensilage well you should not lose more than 10 per cent. of the weight. If you let it get dark, up to 15 per cent. to 20 per cent. The loss of weight for hay in the field was found at Roseworthy College to be about 40 per cent. of the original green weight.

11. *Would stone be suitable for weighting, and what quantity would be required?*

Any convenient material will act as a weight, but as it is necessary to distribute this weight uniformly over the whole surface it is preferable to cover the top of your pit with stout planks and place the weights on top of them—the weight to be not less than 1ewt. per square foot of surface.

*A Few Hints on Ensilage Making.*

As much as possible fill in everything you cut in the course of the day. Do not leave anything over; turn it straight in as quickly as possible.

Whilst you are filling, have the person in the pit continually pressing it down, particularly on the sides, to keep it well packed on the edges.

It does not matter if it rains, providing it does not prevent carting. Rain water will not do any harm.

Fill to about 3ft. or 4ft. above the top. You will find that it will sink, and you can then resume and fill up again. Generally speaking, the heat that is generating at that time will keep mould off. (At Roseworthy Agricultural College a pit 14ft. deep was filled to 2ft. above the top, making 16ft. of vertical measurement. Two days after filling it was found that it had fallen 1½ft. below the walls—a fall of 3½ft.) Therefore, top it up at least once.

Failures are caused by leaving the green stuff out drying. Do not cut more than can be put in in one day; fill in each day and keep tramping it down.

It is an advantage to sprinkle a little salt now and again.

## **EVERY MAN SHOULD MAKE A WILL.**

**FAILURE TO MAKE A WILL** is seldom deliberate. In the majority of cases, men who die intestate have always intended to make a will, but thoughtlessness, forgetfulness, or a reluctance to be directly concerned with a matter that touches the inevitable end of life, have caused them to defer the matter.

**AVOID THE EVILS OF INTESTACY.** Make your will now and appoint this Company as your Executor and Trustee, thus safeguarding your estate and dependants against every avoidable risk.

## WHITE GRUBS.

[By J. DAVIDSON, D.Sc., F.E.S., Waite Agricultural Research Institute, University of Adelaide.]

During the past few weeks several inquiries have been made regarding underground grubs causing damage to pastures and cereals in the South-East area, and to strawberry plants in the Adelaide hills. In every case where specimens were submitted the grubs proved to be the larvae of beetles of the family *Scarabacidae*, which are widely known as "white grubs," the adults being often referred to as cockchafers. The grubs of a number of species of this family are serious root-feeding pests of pasture grasses and allied crops in many countries. Owing to their underground habits their control by practical economic measures is a problem of great difficulty where the infested areas are large.

The destructive species of the family belong chiefly to the group Melonthides, of which the common cockchafer grubs of pastures are well known examples. The sugar cane in Queensland is subject to severe attacks by the larvae of certain species, particularly those of the large chafer (*Lepidoderma albobirtum*). There are hundreds of species of this group in South Australia. The larvae of the different species closely resemble one another in general appearance, and in the present state of our knowledge of the young stages of these insects it is not possible to identify the species concerned from the larval stage only.

The adult beetles vary in size with different species, but they are usually relatively thick-set insects and are readily recognised by the appearance of the antennae. Certain of the segments are flattened and folded in layers, thus forming a conspicuous lamellated club at the end of each antenna. In some cases the beetles may occur in swarms in early summer when they emerge from the pupal cases in the soil. They are night feeders on foliage, and sometimes attack vines and foliage of orchard trees, doing considerable damage. An instance of this kind occurred in the Angaston district in October, 1929, when a species of *Heteronyx* occurred in swarms on a local area of young vines and caused much damage. During the day time the beetles remain in hiding in loose soil or similar situations. The species most frequently met with in South Australia belong to the genera *Heteronyx*, *Diphucephala*, *Scitata*, and *Anodontonyx*. Fortunately many of them appear to confine their feeding habits to native vegetation.

### LIFE HISTORY.

The general features of the life cycle of cockchafer beetles may be briefly outlined as follows:—

The females lay eggs below the surface of the soil in suitable ground in early summer. Some species prefer pasture areas and "white grubs" are likely to be present in grass land broken up for cropping. The young grubs hatch out in about a fortnight, and feed on the roots of suitable plants working from one inch to a few inches below the surface of the soil. The length of time taken for the grubs to attain full development varies considerably with different species. With some species it is about 10 months, but with others it may be two years or more. During this period the grubs are actively at work on the roots of plants, but during the winter period they work deeper into the soil and do not feed so actively. The damage to the crop becomes more evident in spring as the grubs are larger and more active. When the grubs are fully developed they go into a resting pupal stage from which the adult beetles emerge usually in early summer.

The grubs or larvae (Fig. 1) have a characteristic appearance. They are relatively stout with a long, wrinkled body of a whitish or yellowish-white color. When disturbed they curl up into a crescent shape, the end of the body being swollen and dark owing

to the dark contents of the hind intestine. They appear sluggish, but by means of the strong three pairs of legs they can readily work their way through the soil. The head is hard and they have strong biting mouth parts.

Fig. 1.

#### CROPS ATTACKED AND NATURE OF DAMAGE DONE.

While the damage due to white grubs appears more frequently in lawns and pastures, the roots of wheat, oats, potatoes, beans, and strawberries may be attacked. Where present in lawns and pastures the grass in local patches is checked in growth and begins to turn brown and dies. On examination of the soil in these areas to a depth of a few inches the grubs will be found and the roots of the grasses soon to be eaten away. With young cereal crops plants attacked become stunted in growth, usually showing in patches, and eventually die. It will be found that the roots of the plants have been eaten away by the grubs as shown in Fig. 2, which is a photograph of wheat plants attacked by white grubs in Yorke Peninsula, September 20th, 1929. The two plants on the left have not been attacked.

#### NATURAL ENEMIES.

Magpies and crows eat white grubs. Flower wasps (Fam. *Thynnidae*) and Hairy flower wasps (Fam. *Scoliidae*) are valuable insect enemies of these grubs. The female wasp burrows into the ground and when it finds a grub it stings it into insensibility and lays its eggs on it. The young wasp larva which hatches from the egg feeds on the paralysed beetle grub.

#### CONTROL MEASURES.

The control of white grubs is a difficult problem and it is not yet possible to recommend an efficient economic method for dealing with them in a practical manner over large areas. The occurrence of the grubs may be more marked in a crop following grass. Vigorous cultivation will result in the grubs and pupae being exposed to their natural enemies and many of them being killed. A clean fallow will help to starve out the grubs, and the female beetles will not normally select a clean fallow in which

to lay their eggs. If crop rotation is practicable, trials might be made with suitable crops less affected by the grubs. Where small areas in a pasture or cereal crop are found to be infested, measures should be taken to prevent the spread of the damage by destroying the grubs in those areas. A simple method which has given some success in pastures is to roll the infested areas with a very heavy roller when the ground is suitably soft. Many of the grubs will be killed in this way. In a cereal crop the

Fig. 2.

soil of small infested areas may be treated with a soil fumigant. This method may also be used in the case of white grubs attacking garden crops. The method is, however, too costly for use on large areas. Commercial naphthalene, calcium cyanide, and carbon-di-sulphide are generally used. It should be noted that these fumigants are toxic to the roots of the plants, and about a fortnight should elapse after treatment before the area is planted. Where a growing crop is being treated calcium cyanide should not be used. The two other substances referred to are not so toxic as the cyanide, but care should be taken not to place the substances too near the roots of the plants.

Commercial naphthalene is the most convenient substance to use. Its efficiency will depend on the condition of the soil and the amount applied. It should be worked into the soil to a depth of a few inches at the rate of 2ozs. to 4ozs. per square yard. The best results will be obtained when the soil is not too dry. Naphthalene acts as a repellent against soil insects, and while the lighter application of the substance may not kill the grubs it will repel the adult beetles from laying their eggs in the treated soil.

Calcium cyanide may be applied in granular form at the rate of 2ozs. per square yard and worked into the soil to the depth of a few inches. It must be noted that calcium cyanide is very toxic to the roots of plants. It is extremely poisonous to human beings and animals, and must be handled with the greatest care.

Carbon-di-sulphide is a useful soil fumigant and is less toxic to plants than cyanide. It is a highly inflammable liquid, and great care must be taken in using it; and it must not be kept in a warm place. For treatment of root feeding insects it is usually applied by injecting a definite quantity of the liquid into holes in the ground near the plants by means of an "injector" apparatus designed for the purpose. The holes are spaced about 2ft. apart, and the liquid injected to the desired depth. The substance then diffuses through the soil. For the treatment of white grubs this method would be tedious if a comparatively large surface is to be dealt with.

Experimental work in the United States against grubs of the Asiatic beetle (*Anomala orientalis*) infesting lawns has shown that carbon-di-sulphide made up in the form of an emulsion is an efficient fumigant for this purposes. When an emulsion containing 70 per cent. carbon-di-sulphide was diluted 200 times with water and applied at the rate of 3 pints of the diluted emulsion to each square foot of surface, a high percentage of the grubs was killed.

Promising results have also been obtained by top-dressing grub-infested lawns with lead arsenate. Five pounds of lead arsenate mixed with 1bush. of screened soil is applied per 1,000 sq. ft. of area. This method cannot, of course, be applied to pastures on which stock are being fed. Moreover, further research seems necessary to show the influence of arsenic in the soil on plant growth.

It is interesting to note that the Asiatic beetle in Hawaii was controlled by the introduction of a Scoliid wasp (*Scolia manilae*). Until the various species of white grubs which are causing losses in the different areas of South Australia have been investigated, one cannot say what methods of biological control can be applied. The species of beetles concerned appear to be native species, so that one cannot say at present what success can be expected on these lines.

As regards the adult beetles, which are night feeders, when they appear in numbers on orchard trees or vines, a simple mechanical method of jarring the branches so as to shake the beetles into trays of corrugated iron or canvas sheets smeared with tar and kerosine, is useful. Spraying with lead arsenate at the rate of 6lbs. to 100galls. water, to which 1gall. of molasses has been added, will check the damage, but sometimes the beetles are not readily killed with arsenic sprays.

## KYBYBOLITE EXPERIMENTAL FARM.

### REPORT ON FARM CROPS, 1929-30.

[By L. J. Cook, R.D.A., Manager.]

#### THE SEASON.

Agriculturally the season 1929 was a good one in most respects. Weather conditions during most of the season were very suitable to our soils, and practically all crops were sown under really good soil tilth, and maintained continuous healthy growth throughout the winter and early spring. A shortage of late spring and early summer rains, however, caused a poor development of spring-sown crops, and somewhat adversely affected the ripening of autumn-sown crops. Seeding rains were above the average, commenced early in April, and were well distributed throughout April and May. Winter rains were slightly in excess of the average, but were not sufficient at any time to cause over saturation of the soil, and consequently plants received no check in their winter growth. The spring falls were 2ins. less than usual, but were comparatively well distributed, thereby alleviating any bad effects that might have been expected from the reduced rainfall. The early summer rains were also  $\frac{1}{2}$ in. less than the average, and this caused a reduced yield of crops, especially amongst spring-sown cereals and peas.

The following table shows the yields of crops received for the season, in comparison with the mean yields secured since such crops have been under cultivation at Kybybolite:—

TABLE 1.—*Crop Returns for Season 1929-30, Compared with Mean Yields.*

| Crop.            | Period. | Mean Yield. | Average Yield,<br>1929. |
|------------------|---------|-------------|-------------------------|
|                  |         | Bush. lbs.  | Bush. lbs.              |
| Wheat .....      | 1910-29 | 14 47       | 15 24                   |
| Oats .....       | 1910-29 | 19 35       | 10 18                   |
| Barley .....     | 1910-29 | 13 1        | 7 48                    |
| Rye .....        | 1914-29 | 6 49        | 1 52                    |
| Peas .....       | 1921-29 | 11 50       | 4 50                    |
|                  |         | T. C. L.    | T. C. L.                |
| Cereal Hay ..... | 1910-29 | 1 6 66      | 1 7 100                 |
| Ensilage .....   | 1920-29 | 4 2 106     | 6 5 46                  |
| Meadow Hay ..... | 1926-29 | 1 14 82     | 1 15 81                 |

The above table shows that all autumn-sown crops, with the exception of oats, returned yields above the average. Ensilage crops yielded considerably better than the mean yield, whilst meadow and cereal hays yielded a little above the usual. With grains wheat exceeded the mean yield slightly, whilst the result secured from oats was exceptionally low. This was due to rough and unsettled weather experienced immediately before harvest. Crops were rank, and rough weather caused them to be badly lodged, and a large percentage of the grain to shatter. The spring-sown crops, barley, rye, and peas, did not develop well, and yields were disappointing.

The following table sets out the rainfall received at the Farm since 1906:—

TABLE 2.—*Rainfall Distribution at Kybybolite, 1906-1929.*

|                                      | Means,<br>1906-15. | Means,<br>1916-25. | 1926. | 1927. | 1928. | 1929. | Means,<br>1906-29. |
|--------------------------------------|--------------------|--------------------|-------|-------|-------|-------|--------------------|
|                                      | In.                | In.                | In.   | In.   | In.   | In.   | In.                |
| January .....                        | 0.37               | 0.56               | 0.01  | 0.51  | 1.59  | 1.35  | 0.53               |
| February .....                       | 0.93               | 1.10               | 0.43  | 1.20  | 1.74  | 0.22  | 1.00               |
| March .....                          | 1.53               | 0.57               | 0.06  | 0.96  | 0.55  | 0.65  | 0.97               |
| April .....                          | 1.50               | 0.83               | 2.10  | 0.20  | 1.50  | 3.12  | 1.26               |
| May .....                            | 2.52               | 2.61               | 3.17  | 2.92  | 2.24  | 2.16  | 2.57               |
| June .....                           | 3.14               | 2.83               | 1.24  | 1.63  | 2.53  | 3.32  | 2.85               |
| July .....                           | 3.13               | 2.71               | 2.71  | 2.14  | 2.71  | 3.08  | 2.88               |
| August .....                         | 2.67               | 2.61               | 3.31  | 4.02  | 0.90  | 1.84  | 2.62               |
| September .....                      | 2.96               | 2.69               | 1.79  | 0.91  | 3.12  | 1.75  | 2.67               |
| October .....                        | 1.80               | 1.92               | 2.27  | 0.52  | 4.47  | 1.50  | 1.91               |
| November .....                       | 1.55               | 1.51               | 0.68  | 2.06  | 0.99  | 0.97  | 1.47               |
| December .....                       | 1.21               | 1.10               | 0.83  | 1.31  | 0.17  | 1.66  | 1.13               |
| Total rainfall .....                 | 23.31              | 21.04              | 18.60 | 18.38 | 22.51 | 21.62 | 21.86              |
| Total "Useful" rain, April-Nov. .... | 19.27              | 17.71              | 17.27 | 14.40 | 18.46 | 17.74 | 18.23              |

The total rainfall of 21.62ins. for the year is approximately the average received during the past 24 years, and except for the light spring rains the distribution was good.

TABLE 3.—*Distribution of "Useful Rain," Kybybolite, 1929.*

#### CROPS.

On account of the much-improved pasture of the Farm, the increasing of the grazing livestock, and a reduction of manual labor, the area sown to crops was further reduced. One hundred and twenty-eight acres were sown to cereals and peas on the area set apart for testing various rotational systems of cropping. The usual area was devoted to turnips for winter grazing, whilst the main fields of the Farm, outside the experimental areas, were top dressed. Approximately half the Farm is now sown to Subterranean Clover and Wimmera Rye Grass pasture.

#### TURNIPS.

As usual, three fields sown to Mammoth purple-top turnips during the spring of 1928 were grazed in the winter months of 1929. The crops germinated well and made a good stand. The summer rains of 1928 and autumn showers of 1929 were sufficient to maintain the crops, and the good April falls caused a very good development of roots by June. The fields were grazed in the usual way, without hurdling, and carried the equivalent of 2.54 sheep per acre per annum, or approximately 30 sheep per acre for one month during mid-winter. The result is slightly better than the mean carrying capacity secured from turnip crops during the past eight seasons. The following tables show the grazing received from the various fields for 1929, and the feeding results secured from turnip crops for the past eight years.

## ENSILAGE CROPS.

Cereal crops generally made bulky and thick growth, and consequently yields of ensilage were higher than usual. The bulk of ensilage was made from wheat crops that were following peas in the rotational tests.

The following tables show the returns of ensilage secured for 1929 from various fields, and also the returns for the past 10 seasons:—

TABLE 6.—*Ensilage Yields, Kybybolite, 1929.*

## CEREAL HAY CROPS.

On account of the reduced area of cropping on the Farm, and also to the fact that Meadow Hay is now available as dry feed for the dairy herd, the requirements of cereal hay are much less. Consequently only 21 acres were this year cut for hay. Some useful yields were recorded from various fields, and are shown in accompanying tables:—

TABLE 8.—*Cereal Hay Yields, Kybybolite, 1929.*

## MEADOW HAY.

The growth of Subterranean Clover and grass was good again this year, and as a large surplus was available in the pasture fields, a much greater quantity of this fodder was conserved as hay. The use of the improved push rake and hay press was secured, which enabled over 61 tons to be cut, cured, and pressed into bales. This meadow hay is proving particularly useful for feeding to the dairy herd during the colder months of the year, and when pressed into bales the handling of this bulky fodder is greatly economised. The following tables show the yields of meadow hay secured from various fields, together with the yields for the past four seasons from land fertilised with water soluble phosphates. Purely experimental areas have not been included:—

| Means .... | 20-28          | 16-97     | 61-34  | 106          | 10 | 42 | 1               | 14 | 82 |

With reference to Table 10, it should be noted that the western section of Field No. 18 was mown three weeks later than the centre section, and consequently the weight of hay secured was considerably lighter, although there was little noticeable difference in the two stands of pasture. Also Field No. 6B contained  $7\frac{1}{2}$  acres of a good stand of Subterranean clover, and 2 acres of only a medium stand of crimson and natural clovers. The yield of approximately  $2\frac{1}{2}$  tons per acre from the centre section of Field No. 18 is particularly satisfactory, especially as this same area returned a yield of 38cwts. per acre the previous season, 1928.

For the four seasons, 1926-29, it is interesting to note that the average yield of cereal hay secured on the Farm has been 1 ton 14cwts. 2lbs. per acre, as against 1 ton 14cwts. 82lbs. per acre received from meadow hay.

#### OAT CROPS.

Forty-four acres were sown to oats in the various rotation tests with the Algerian variety. On account of the reduction of staff the growing and testing varieties of oats has had to be discontinued. The crops made good growth, and promised to yield well. With the exception of one small field, and headlands, 40 acres were left for harvesting for grain.

Unfortunately rough weather occurred immediately before oats were sufficiently ripe for harvesting and caused considerable loss of grain through heavy lodging of crops, and subsequent shattering of grain. Especially was this the case in Field No. 20B, which had been under clover pasture for three seasons, and grew a particularly heavy and bulky crop. The stubbles were heavily stocked, and carried the equivalent of 5 sheep per acre for the first three months of 1930.

The following table sets out the returns received from oat crops since 1910:—

TABLE 12.—*Oat Returns, Kybybolite, 1910-29.*

## BARLEY CROPS.

Cape barley was sown in the three fields in the springtime in the various rotations, following the grazing of turnips. Seeding was done in August under good soil tilth and weather conditions, but a rather heavy rain fell a few days after seeding, causing a fair percentage of the grain to rot. On account of the shortness of the season, the thin crops failed to stool or develop well, and unsatisfactory yields were recorded. This is the poorest result received from barley since this crop has been grown in systematic rotation following the good, cleaning root crop, turnips.

The average yield of barley for the past eight seasons, since this system has been in operation, has been 22bush. 18lbs. per acre, in comparison with the general average return of 13bush. 11lb. per acre.

The following table shows the returns of barley received since 1910:—

TABLE 13.—*Barley Returns, Kybybolite, 1910-29.*

## WHEAT CROPS.

Twenty-six acres of wheat were harvested for grain, and all, with the exception of 1 acre of spring sown, was grown in Field No. 20E following three seasons of clover pasture. The wheats made really good growth, developing into tall, bulky crops, which yielded heavily in straw, but somewhat disappointing in grain. Of the seven varieties grown, Sultan yielded best with 20bush. per acre, followed by Leak's Rust Proof and Federation with 18bush. and 17½bush. respectively.

The following table shows the returns received from the various varieties:—

TABLE 14.—*Wheat Fields, Kybybolite, 1929.*

#### RYE CROP.

A plot of rye was included amongst the spring-sown cereals in Field No. 6r. It suffered much worse than barley sown under similar conditions. The next table shows the yields of rye secured since 1914:—

TABLE 16.—*Rye Returns, Kybybolite, 1914-29.*

| 1928 ..... | 22-51                     | 18-46                          | 1-99            | 22 49                         | 11 28                            |
| 1929 ..... | 21-62                     | 17-74                          | 1-89            | 3 32                          | 1 52                             |
|            | 20-41                     | 17-30                          | 73-51           | 501 22                        | 6 49                             |

(In compiling above figures rye has been taken as weighing 60lbs. per bushel.)

#### PEA CROPS.

Peas were grown in two fields in the rotation series, but like the spring-sown cereals they suffered from the shortness of the season, and yields were unsatisfactory. The yields received are shown in the table following.

TABLE 17.—*Pea Yields, Kybybolite, 1929.*

| Variety.              | Field<br>Grown. | Area.<br>Acres. | Total<br>Yield.<br>Bush. lbs. | Yield per<br>Acre.<br>Bush. lbs. |

The following table summarises generally the returns of the chief crops harvested for 1929, showing the average yield per acre, their values at current rates, also as stock food, as compared with hay at £3 per ton. The figures are based on tables prepared by the Director of Agriculture (Professor Arthur J. Perkins):—

TABLE 19.—*Value of Crops Harvested, Kybybolite, 1929.*

## EXPERIMENTS WITH VARIOUS SOIL CORRECTIVES.

Since 1925 Fields Nos. 16b and 16c have been utilised to test the use of Lime and Gypsum against High Grade 82 per cent. Rock Phosphate and Superphosphate in a two-course rotation of crops—peas and wheaten hay.

The pea crops were ploughed under as green manure during 1926 and 1927.

This season Subterranean Clover was sown with the wheat crop, and it has been decided to discontinue with the pea crop. Some of the plots have become badly infested with sorrel, which the clover should check, and at the same time interesting results should be obtained from the effect of lime and gypsum on the clover crop.

The following table shows the yields of wheaten hay secured for the past five seasons from the respective plots:—

TABLE 21.—*Experiments with Various Soil Correctives, 1925-29.*

| Plot. | Fertiliser per Acre.                         | Wheaten Hay Yield per Acre. |    |    |       |    |     |       |    |    |       |    |    |       |    |    |       |    |     |
|-------|----------------------------------------------|-----------------------------|----|----|-------|----|-----|-------|----|----|-------|----|----|-------|----|----|-------|----|-----|
|       |                                              | 1925.                       |    |    | 1926. |    |     | 1927. |    |    | 1928. |    |    | 1929. |    |    | Mean. |    |     |

| 3.    | 1cwt. 45% Super. . . . .                     | 1                           | 5  | 84 | 1     | 2  | 105 | 1     | 9  | 14 | 2     | 8  | 84 | 1     | 3  | 28 | 1     | 9  | 108 |
| 4.    | 1cwt. 82% Rock<br>Phosphate . . . . .        | 0                           | 15 | 98 | 0     | 14 | 91  | 1     | 13 | 98 | 2     | 4  | 84 | 0     | 19 | 98 | 1     | 5  | 94  |
| 5.    | 5cwt. Gypsum and<br>1cwt. 45% Super. . . . . | 0                           | 19 | 70 | 1     | 3  | 0   | 2     | 0  | 56 | 1     | 17 | 84 | 1     | 7  | 98 | 1     | 9  | 84  |

The above results for the five seasons show that Plot No. 2, dressed with Lime and Superphosphate, has returned the greatest yield of hay, viz., 2½cwt. per acre greater than that dressed with Superphosphate only.

This increase is insufficient to warrant the application of 5cwt. Lime, costing approximately 12s. 6d. per acre. However, the stubble feed and early winter growths on Plot No. 2 have been very much greater than from other plots, giving extra useful grazing, which is solely attributable to the Lime. As these plots are not fenced individually, no record of this value is available.

## EXPERIMENTS WITH VARIOUS PHOSPHATIC FERTILISERS ON CEREALS IN CONJUNCTION WITH SUBTERRANEAN CLOVER.

Quantities of Ephos Phosphate and Bone Manure have been given to the Department by distributing firms, and these were again tested in Fields Nos. 7A, 7b, and 7c. The plots are set out according to the phosphatic content of the fertilisers—each one being tested in equivalence in phosphoric anhydride—with applications of both 90lbs. and 180lbs. respectively of 45 per cent. Superphosphate. Field No. 7b carried the cereal, an oat crop this year, whilst Nos. 7A and 7c were top dressed with similar quantities of fertilisers, with the exception of lime, the one application of 1 ton of lime per acre given to Plot No. 7, being intended as sufficient for at least six seasons. The

## Fordson Economy

saves money for the farmer

**T**HE most successful and prosperous farmers in Australia today are those who have realised that Fordson farming shows big savings over horse-team work and that of heavier, more expensive tractors.

The Standard Fordson

**£220**

at nearest Ford works

*Price subject to Sales Tax*

The New Fordson Tractor, with its 36% increase in power and its many mechanical improvements, is everywhere reducing farm production costs. It will do the work of an 8-horse team with effortless and untiring energy, using either petrol or kerosene.

A Queensland owner of a new Fordson, ploughs at less than 10d. per acre . . . . . A New South Wales farmer using a heavily-weighted 6-leaf harrow, found that his Fordson worked 7 acres to the gallon of kerosene. Every day, from every part of Australia, comes similar enthusiastic praise of the Fordson's remarkable economy. See your nearest Ford dealer. Ask him for facts and figures concerning the Fordson at your own farming operations.

fields are being worked under a three-course system of rotation, consisting of one cereal crop, followed by two years of Subterranean Clover. The second cycle of crops is now being grown, so that Field No. 7a this year carried its first cereal crop following clover. Algerian oats were used, and produced good stands on the plots, whose yields, however, were unfortunately somewhat reduced by the effects of rough weather during harvesting. On account of shortage of available labor, we were again unable to harvest the clover for hay, and as individual plots are not fenced no grazing figures are available. The following table shows the yields of wheat received during 1927 and 1928, and of oats received for 1929:—

TABLE 22.—*Experiments with Phosphatic Fertilisers on Wheat and Oats.*

## EXPERIMENTS WITH SPECIAL FERTILISERS ON WHEAT.

A test of special fertilisers was carried out on 1-acre plots in Field No. 20E, using Leak's Rust Proof wheat. The land had been under clover pasture for three seasons. The following table shows the fertilisers applied, their analyses, and yields for the past three seasons:—

TABLE 23.—*Experiments with Special Fertilisers on Wheat, 1927-29.*

## ROTATION OF CROPS EXPERIMENTS.

**Rotation A.**—This five-course rotation of 30-acre fields, consisting of wheat, oats, and three years Subterranean Clover was commenced in 1923. The following table shows the results received for the past seven seasons:—

TABLE 24.—Five-Course Rotation of Crops, Kybybolite, 1923-29.

| Year.    | Wheat.          |       | Oats.           |       | Subt. Clover.   | Subt. Clover.   | Subt. Clover.   |

| Means.   | 14              | 27    | 16              | 22    | 2-51            | 2-56            | 2-82            |

Subterranean Clover is easily the most valuable crop in the above series, and the table shows the consistency of growth obtained from the plant. From all the clover fields in the past six years this series has exceeded in carrying capacity an average of 2½ sheep per acre annually. This means that on the 150-acre block of five fields we are able to carry 225 sheep annually, as well as cultivate 60 acres, and have the stubble feed from the crops to spare.

**Rotation B.**—A six-course rotation has been carried on in a series of 2-acre fields since 1918. The order of cropping is as follows:—Wheat, Oats and Vetches, Turnips, Barley, Rye Grass and Clover for two years. The second cycle of crops has now been completed. The yield of crops in this rotation are as follows:—

TABLE 25.—Six-course Rotation of Crops, Kybybolite, 1918-1929.

| Year.     | Wheat.   |    | Oats and Vetches. |    |     | Turnips.<br>Sheep<br>per Acre. | Oats or Barley. |                   | Rye Grass and Clover.<br>Grazing. |              |

EXPERT ADVICE ON GRASSES AND CLOVERS.

In Table 25 Alsike Clover with both Italian and Perennial Rye Grasses have been tried. The Perennial Rye Grass has given better growth and feed than the Italian, and consequently the latter has not been sown in the mixture during the last two seasons. The most successful crops in the rotation have been turnips and spring-sown barley. The former has carried the equivalent of 3.16 sheep per acre over the past eight seasons, which is approximately  $\frac{1}{2}$  sheep per acre better than the average for turnip grazing, whilst barley has yielded 25bush. per acre, which is 3bush. better than the farm average for the same period.

*Rotation C.*—The Norfolk four-course rotation—turnips, barley or oats, peas, and wheat—is being tested in 4-acre fields. The test was commenced in 1919, and the third cycle of crops is now being grown. The following table shows the returns received for the past 11 seasons:—

TABLE 26.—*Four-Course Rotation of Crops, Kybybolite, 1919-29.*

Of the above crops, the average yields of all, except peas, have yielded above the mean yields of the Farm. Yields of barley and hay have been particularly good, being 5bush. and 8cwts. per acre respectively better than Farm averages for the same periods.

*Rotation D.*—A six-course rotation—peas, wheat, turnips, oats or barley, clover, grazing oats—is under test in 9-acre fields. The series was commenced in 1920, and the returns to date are as follows:—

TABLE 27.—*Six-Course Rotation of Crops, Kybybolite, 1920-29.*

| Means .    | 13 12        | 1 15 86 (hay)<br>21bush. 13lbs. (wheat) | 2-16                           | 1 12 57      | 1-61                          | 18 15      |

In the above rotation, trials have been made with various annual clovers, with but little success, and consequently since 1928, Subterranean Clover has been sown, and it is proposed in future to discontinue sowing peas, and reduce the cereal crops in the series. The order of cropping in future will be turnips, barley, cereal hay, Subterranean Clover, grazing (2 years), clover hay.

## RED COMB EGG ASSOCIATION.

## OFFICIAL SINGLE TEST.

## EGG-LAYING COMPETITION, 1930-31.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1. White Leghorns—204 birds; Black Minorcas—3 birds.  
Section 3. Black Orpingtons—30 birds. Section 4. Rhode Island Reds—6 birds.

Twelve Months Test. To start on April 1st, 1930.

Section 1.—White Leghorns, 1 to 204; Black Minorcas, 205 to 207.

## "HERD TESTING" GOLD MEDAL COMPETITION.

[By Mr. P. D. JEFFERY, Chief Clerk, Department of Agriculture.]

Three years ago the United Stud Dairy Cattle Breeders' Association of South Australia was instrumental in arranging an annual Butterfat Output Competition among those of its members whose herds were under official test, and during each of the three years, Government has offered a Gold Medal for the owner of the winning herd.

In the first year's competition, the herd of Mr. C. J. Morris, of Monteith, secured top place, with an average butterfat production of 556.58lbs.; and for the second year the winning herd was that of Mr. J. A. J. Pfizner, of Hampden, the average output being 456.81lbs.

Results of the third year's competition are now available, and from the summary which is attached hereto it will be seen that Mr. C. J. Morris is once again the successful competitor. On this occasion his herd has averaged 496.69lbs. butterfat.

For the information of competitors and those who are not yet associated with Departmental Herd Testing schemes, it might be advisable to give a rough idea of the conditions under which the Competition is carried out, otherwise some of the figures in the attached summary will not convey their full meaning.

The conditions are somewhat as follows:—

1. No herd of less than 6 cows is eligible to compete.
2. In a herd of more than 6 cows, the owner has the right to withhold from competition 25 per cent. of the herd.
3. One in every six or part thereof cows in a herd must be a matured animal.
4. The butterfat standards as set by Government for the various ages of cows are not used in this competition, but instead handicaps arranged by the competitors themselves are brought into operation. These handicaps are:—

|                                                | Butterfat.<br>Lbs. |
|------------------------------------------------|--------------------|
| For heifers under 2 years at calving . . . . . | 80                 |
| Two and under 3 years . . . . .                | 60                 |
| Three and under 4 years . . . . .              | 40                 |
| Four and under 5 years . . . . .               | 20                 |
| Five years and over . . . . .                  | Nil                |

## STATE OF SOUTH AUSTRALIA.

## VARIETIES OF WHEAT SOWN, SEASON 1929-1930.

[W. L. JOHNSTON, Government Statist.]

The Government Statist reports that 212 varieties of wheat were reported as sown for the wheat crop of the season 1929-1930. The total area sown for grain, hay, and fodder was 3,987,310 acres, of which the varieties sown were not specified for 141,356 acres.

Particulars of the sixteen most popular varieties are given at foot hereof. From these it will be seen that Gluyas (16.30 per cent.) and Late Gluyas (10.61 per cent.) occupy first and second place, and accounted for more than one-quarter of the total area sown. It is interesting, further, to note that one-half of the sown area was sown with the first five varieties: Gluyas, 16.3 per cent.; Late Gluyas, 10.6 per cent.; Federation, 8.7 per cent.; 7.6 per cent.; and Currawa, 7.3 per cent.; total, 50.5 per cent.

*The three leading varieties favored in each of the divisions were:—*

|                  |               | %   |                     | %   |          | %   |
|------------------|---------------|-----|---------------------|-----|----------|-----|
| Central .....    | Nabawa ....   | 13  | Gluyas .....        | 12½ | Ford ... | 11  |
| Lower North ...  | Federation .. | 13  | Nabawa .....        | 13  | Gluyas.. | 10½ |
| Upper North ...  | Federation .. | 30  | Gluyas .....        | 10  | Daphne . | 9   |
| South-Eastern .. | Federation .. | 36½ | Huff's Imperial ... | 14  | Major... | 10½ |
| Western .....    | Late Gluyas . | 27  | Gluyas .....        | 25  | Ford ... | 6   |
| Murray Mallee .. | Gluyas.....   | 16½ | Currawa .....       | 9½  | Sultan . | 9   |

*Varieties Increased.*—The following leading varieties show increases:—Nabawa, 288,878 (116,220) acres; Gallipoli, 72,520 (39,581); Waratah, 47,677 (26,631); Late Gluyas, 423,116 (331,737); King's White, 41,256 (34,337); and of the lesser: Aussie, 11,469 (5,206); Bena, 15,706 (7,457); Ghurka 3,258 (918); Huguenot, 8,044 (3,580); and others.

*Varieties Decreased.*—Federation, 347,738 (393,293); Ford, 304,296 (376,451); Currawa, 291,012 (325,480); also Yandilla King, Silver Bart, Minister, Queen Pau, and others.

*Sixteen Leading Varieties of Wheat Sown 1929-1930 and 1928-1929.*

## TOP-DRESSING OF PASTURE LAND.

[W. L. JOHNSTON, Government Statist.]

There has been considerable expansion since 1924 in the area of pastoral land top-dressed. The following return setting forth the chief districts of the State in which lands are top-dressed has been prepared with a view to noting the effect of same on the numbers of sheep carried. In many cases it will be observed that the sheep flocks have substantially increased, and no doubt top-dressing has been the principal reason for this.

*Acreage Top-dressed.*—From a total of 67,124 acres top-dressed in 1924 the area top-dressed during the year increased to 302,114 acres in 1929. The principal districts are:—District council Onkaparinga, 4,789 acres to 12,570 acres; district council Mount Gambier, East and West, from 972 acres to 18,890 acres; district council Penola, from 4,289 acres to 20,379 acres; and district council Naracoorte, 9,796 acres to 50,614 acres.

*Manures Used.*—In the season 1924 4,080 tons of artificial fertilisers were used for top-dressing 67,124 acres, and in 1929 15,761 tons on 302,114 acres.

*Sheep Carried.*—There were 1,020,293 sheep in 1924 in the special districts tabulated when only 39,973 acres were top-dressed, and for the same districts in 1929 when the top-dressed acreage had increased to 210,295 acres the number of sheep had increased to 1,430,066.

*Principal Top-dressed Pasture Lands and Sheep Carried.*

| Selected Districts.         | Acres Top-dressed during each Year. |         |         | Number of Sheep as at December 31st each Year. |           |           |

## TOMATO DISEASES IN SOUTH AUSTRALIA AND HOW TO CONTROL THEM

with special reference to Glasshouse Tomato Culture.

---

[By GEOFFREY SAMUEL, M.Sc., Plant Pathologist, Waite Agricultural  
Research Institute, University of Adelaide.]

[Continued from page 166, *Journal of Agriculture*, September, 1930.]

---

### THE NATURE OF DISEASE.

Diseases may be of the following kinds:—

**VIRUS DISEASES**, in which an infective sap is transmitted from plant to plant either directly on the fingers of workers (*e.g.*, *Mosaic* and *Streak* diseases) or by means of insects (*e.g.*, *Spotted Wilt*, carried by the black carnation thrips).

**BACTERIAL DISEASES**, in which minute living organisms, the bacteria, infect plants and multiply inside them in immense numbers. They may be transmitted on the fingers of pruners or gain entrance from the soil through wounded roots (*e.g.*, *Bacterial Wilt* disease).

**FUNGUS DISEASES**, in which the disease results from the attack of parasitic moulds or micro-fungi. These parasitic fungi may attack the roots (*e.g.*, *Verticillium Wilt*); or the stems of seedlings at ground level (*e.g.*, *Damping-off*); or the leaves (*e.g.*, *Leaf Spot* and *Early Blight*); or the fruit (*e.g.*, *Phoma fruit-rot*). Fungus diseases are usually spread by minute spores, which may be blown about in the air, or be carried in water or soil.

**NON-PARASITIC DISEASES**, a miscellaneous group of troubles in which may be placed for convenience any abnormal condition which is not due to the attack of some definite parasitic or infectious organism, such as a virus, bacterium or fungus (*e.g.*, *Blossom End Rot*, *Sunburn*, &c.).

**EEL-WORMS** or **NEMATODES**, which attack the roots, causing big clubby swellings. The eel-worms last over from season to season as eggs in the soil.

**INSECT PESTS**, the best known of which to the tomato grower are the "white fly" and the "green caterpillar."

### VIRUS DISEASES.

Virus diseases are becoming an extremely important class of disease, as the severity of tomato spotted wilt in Australia and of sugar-beet curly-top and aster yellows in America, as well as many other diseases of economic importance, will bear witness. Virus diseases are also particularly difficult to investigate, because the casual agent, whatever it is, is so small that it cannot be seen with the highest powers of the microscope. We know, however, that the sap from a diseased plant, when it is inoculated into a healthy plant, will cause the disease to appear in this healthy plant after an "incubation period" of about seven to 14 days.

The infectiveness of the sap varies very much in different virus diseases. In tomato and tobacco *mosaic* and in tomato *streak* it is very infective, and the small amount which might be carried on the fingers after pruning a diseased plant would be quite sufficient to give the disease to several healthy plants pruned immediately afterwards without washing the hands.

In other cases, however, and particularly those cases in which an insect is the carrier of the disease, the sap does not appear to be very infective directly on the fingers. In fact, in the case of aster yellows, it is said that the disease cannot be transmitted in any other way than by the insect carrier, which is a leaf-hopper. Tomato spotted with wilt falls in this class, and practically the whole of the spread of the disease in South Australia is the result of the sucking activities of the black carnation thrips, which is the special insect vector of this disease.

*Control methods* for virus diseases must be based upon our knowledge of these points particularly :—

- (1) A diseased plant is full of an infective sap.
- (2) This may be carried on the fingers and infect healthy plants in some cases, or
- (3) It may be carried about by some sucking insect.
- (4) A plant which has been infected by fingers or by insect bite shows no symptoms for the first 10 to 14 days or so, although its sap may be already infective during this time.
- (5) Plants of closely related families or weeds may carry the virus also.

The information given in these five points would suggest the following methods for the control of virus diseases in general in tomato glasshouses (further details are given in the separate treatment of each disease) :—

- (1) Keep a keen eye open for diseased plants. Unfortunately it is often the most vigorous plants which become affected. When the earliest symptoms of a virus disease are noticed mark the affected plants, but do not touch them until the end of the day.
- (2) At the end of the day remove all marked plants carefully and bury them or burn them. Then wash the hands with soap and water, and replace with healthy seedlings.
- (3) Control insects by spraying or dusting with nicotine sprays or dusts.
- (4) Do not prune for a fortnight after virus diseases are noticed, but continue to mark and replace affected plants each day and control insects. The plants which become affected during this fortnight were probably already infected when the first ones were noticed, and the idea of a fortnight's cessation of pruning is to avoid the possibility of carrying on the sap from such infected plants which are still in the "incubation period" and not yet showing symptoms.
- (5) Avoid growing potatoes near the glasshouse, and also keep down all weeds, especially those closely related to the tomato, such as black nightshade.

The buying of seedlings raised on some other property always brings with it the risk of introduction of virus diseases, as well as of other diseases.

## BACTERIAL DISEASES.

Bacteria are exceedingly minute living organisms. Those which attack plants have a simple rod-shaped form (Fig. 1a). When under suitable conditions for growth they multiply by dividing into two; soon each of the two divides into two again, so that there are four; and so on. Starting with one bacterium, if it divides into two in half an hour, and the progeny continue to divide every half-hour, at the end of 24 hours there would be 280,000,000,000,000. Actually, of course, competition for food would take place before such numbers were reached, but they serve to show the immense powers of reproduction of these lowly organisms.

FIG. 1. (a) A small group of bacteria, showing their rod-shaped form and how they multiply by dividing into two. Magnified 2,000 times.

(b) Part of a thin section across the stem of a tomato plant diseased with bacterial wilt. Magnified 250 times, so that only a very few of the cells can be shown; at this magnification the whole stem would be 10ft. across and a 1,000ft. high. The section passes across the cavity of two of the water-conducting vessels as well as across a number of the smaller strengthening cells. One of the water-conducting vessels has been blocked up by masses of bacteria. In a diseased plant on this scale columns of bacteria might extend in the water conducting tubes for 500ft. to 1,000ft. up the plant as thickly massed as drawn; this will give a faint idea of the enormous numbers of germs in a diseased plant, and how many could stick to one's finger, which would be about as thick as the trunk of a very big tree.

There are very many kinds of bacteria. Some live only on non-living organic matter, such as those which decompose meat or those which turn milk sour, or those which bring about various chemical changes in the soil. Others are active parasites of animals or man and cause serious diseases; still others cause plant diseases. In each case, however, it is a definite species of bacterium which causes a definite disease. Among plants, for example, the bacterium which causes bacterial blight of walnuts is quite a different one from that which causes bacterial wilt of tomatoes.

If, therefore, the bacterial wilt of tomatoes appears in a glasshouse where it has not been seen before, the bacterium which is the cause of the disease must have been introduced there in some way—either by buying seed or seedlings from some outside infected source, or perhaps by some visitor who has previously walked through a diseased house, or by water from some infected property higher up from which drainage water comes down, or in some other way.

When disease-producing bacteria come in contact with the host plant which they normally attack, and gain entrance to the tissues inside (usually a small wound is necessary to enable them to penetrate) they multiply very rapidly. The food material which enables them to grow and multiply

is absorbed from the tissues of the host plant. The bacteria in their growth excrete ferments which dissolve the substances in the cells of the host plant, so that the infected parts soon collapse. A slimy liquid frequently oozes out when the infected part is cut across, and this liquid contains millions and millions of the bacteria. It is thus readily to be understood how a person pruning a diseased vine could get thousands of bacteria on his fingers when he pulled off a shoot, and could place some of these bacteria in a very suitable place for infection when he pulled the shoots off the next healthy plant. It is, in fact, frequently noticeable that when bacterial wilt breaks out in a house a number of plants next to one another along a row are first seen to be diseased. There is little doubt in such a case that the bacterium has been carried along on the fingers of the pruners.

*Control methods* for bacterial disease in a glasshouse must, therefore, be based mainly on strict precautions for plant hygiene in order to prevent the bacteria being carried from plant to plant. This includes removal and destruction of diseased plants as soon as seen (as described before, this should be done at the end of the day, and the hands thoroughly washed with soap afterwards); a period of cessation of pruning to allow already infected plants to show up; the avoidance of replanting in holes from which diseased plants have been removed, for the bacteria live in soil and can gain entrance through wounded roots; or, if it is particularly desired to replant, watering the soil well and watering in the seedlings with Cheshunt mixture. On no account should diseased plants be left in, and the pruners go along the rows as if no disease were there. In this way they are certain to spread the trouble to other healthy plants.

#### FUNGUS DISEASES.

The fungi which cause plant diseases are microscopic, and it is usually only their effect on the plant, such as rotting of the roots, diseased spots on the leaves, &c., &c., which makes their presence evident to the naked eye. In all such cases, however, a scientific examination under the microscope reveals the fungus which is the cause of the trouble to be present in the diseased parts.

Fungi are usually spread by microscopic "spores" which blow about in the air. These spores germinate in moisture, and the fungus threads which grow out from them are capable of penetrating and growing within a suitable host plant, thus bringing about a state of disease.

Their action can best be explained by following what happens in a specific disease. The Early Blight disease of the leaves, which will be described later, may be taken as an example. In this case the spores are very characteristic in shape (Fig. 2a), consisting of a row of brownish cells tapering to a long point. They are too small to be seen by the naked eye, however, and are readily blown about in currents of air. They can easily settle on a tomato leaf and stick to it, just as small particles of dust stick to leaves. If moisture is then deposited on the leaves, such as frequently occurs in the early morning after cold nights, the spore absorbs moisture and begins to germinate. One or more thin, delicate "germ-tubes" push out from the spore, and soon begin to penetrate the surface of the leaf (Figs. 2b and c). Once they have actually penetrated through the outer cell-wall and arrived within the cell cavity just beneath where they lie on the leaf, they can begin to absorb food material from the plant. The fungus

threads continue to grow and branch and penetrate neighboring cells, and as they grow they secrete ferments which dissolve the tissues of the plant and make them available as food to be absorbed by the fungus. The effect on the leaf is that a "diseased spot" appears, where the tissues of the leaf are collapsed, but a microscope can still reveal the threads of fungus growing within the dead tissue.

The spot gradually enlarges owing to the continued growth of the fungus. Finally comes the stage when the fungus is nearly full grown and it proceeds to form a crop of spores on special spore-bearing branches which are pushed through the surface of the leaf (Fig. 2d). Diseased spots on leaflets such as are to be shown in Fig. 23, which, of course, have each arisen from the germination of a single spore, if examined under the microscope, would be found to be covered with a crop of some hundreds

FIG. 2.—(a) Two spores of the Early Blight fungus.  
 (b) The way in which a spore germinates in water.  
 (c) The way in which the fungus penetrates into the plant. The spore is lying on the surface of the leaf, the cells of which are shown greatly magnified. It has germinated in some moisture on the surface, and the germ-tube has penetrated through the outer wall and is now growing and branching within the cells of the leaf.  
 (d) A thin section through the edge of a diseased spot such as one of those in Fig. 23. Healthy leaf tissue is at the left, and the shrunk tissue of the diseased spot with the fungus threads growing through it is on the right. Actually, the amount of leaf-tissue shown is about as wide as a small pin's head. The fungus has been growing for some time in the leaf and some of the fungus threads are already pushing out through the surface and forming a crop of spores over the diseased spot. At this magnification the diseased spot would be 5 ft. across, so that only the edge of it can be shown and a very few of the spores it produces. Some two to three thousand spores may be produced on a single diseased spot, which originated from infection by single fungus spore as in (c).

of fungus spores just like those in Fig. 2. These are easily detached and blown about, and are capable of germinating and reproducing the disease according to the cycle just described.

It will be easily understood from the above how a few primary infections can soon produce sufficient spores to cause quite an epidemic. It is for this reason that the tomato grower should get the habit of noticing the smallest sign of disease, so that he can take immediate steps to combat it

before it spreads too far. Even the picking off of odd diseased leaflets in the early stages may be of considerable value in control, but it becomes impossible, of course, when there are many of them.

The effectiveness of spraying for the control of fungi depends upon the fact that the healthy plant is coated all over with a fine layer of poison. This acts as a protection against infection, for if spores fall on the leaves and sufficient moisture comes to germinate them, the germ tubes absorb some of the poison and are killed before they can penetrate into the leaf. Spraying, of course, is no good after infection has occurred, for the fungus is then inside the leaf where the spray cannot reach it. Dusts act in the same way as sprays, and are often easier to apply in glasshouses. The important point to realise in using dusts and sprays is that the fungicide acts only as a protection to healthy growth, and that after a week or two when fresh growth has occurred at the top of the plant this will be unprotected by any covering of poison.

The *general control methods* for fungus diseases may therefore be set down as:—

- (1) strict attention to plant hygiene, including removal and destruction of diseased material where possible, for this may be a source of thousands of new spores. Especially at the end of the season an effort should be made to clean up as thoroughly as possible and burn all refuse;
- (2) keep a sharp look-out for the first sign of the appearance of any fungus disease; and then
- (3) put on a protective covering of spray or dust as soon as there is a possibility of a disease spreading;
- (4) try and remedy any factors which may tend to increase the spread of the disease. It is possible that something may be done to reduce the humidity, or to stop the drip of rain in certain places, or sometimes disease is worse because a susceptible variety is grown and a change of variety will be of value.

Fungus diseases are of such great variety, however, that general remarks are not sufficient, and the recommendations under each separate disease should be consulted. Soil fungi, for example, which attack the roots, cannot be checked by spraying, but the watering of Cheshunt mixture on to the soil may be of benefit in certain cases.

#### § NON-PARASITIC DISEASES.

This is simply a convenient group heading for a number of troubles which are not caused by parasitic or infectious organisms, but which in most cases are due to something being wrong in the growing conditions. For example, a short period of drought may cause a rotten patch to appear at the end of a number of fruits—the so-called Blossom End Rot and various other non-parasitic troubles will be discussed in a subsequent issue.

#### EEL-WORMS.

(A special section will be devoted to eel-worms later.)

## INSECTS.

When insects attack plants they are usually referred to as *pests*, and not as *diseases*. The insect pests which worry the tomato growers may be set down as:—

|                 |                                                                            |
|-----------------|----------------------------------------------------------------------------|
| Chewing insects | { cutworms.<br>green caterpillars or "grubs."                              |
| Sucking insects | { green aphid.<br>white fly.<br>surface mite (the cause of "golden stem"). |

Thrips (sucking insects), at least one species of which, the black carnation thrips, is responsible for spreading the spotted wilt disease, do not become sufficiently numerous in South Australia to be a pest in themselves; it is the serious nature of the virus disease which they carry and inoculate into plants which is responsible for the losses involved, and thrips as carriers of the virus are discussed under the heading of spotted wilt.

*Control Methods for Insect Pests.*—These may be briefly stated here as arsenic-containing sprays, dusts, or baits for chewing insects, and nicotine-containing sprays or dusts for sucking insects (though cyanide fumigation is more efficient against white fly).

Insecticides containing arsenic are known as *stomach poisons*, for the arsenic is taken in with the parts of the plant which are eaten, and acts as an internal poison. Insecticides containing nicotine are known as *contact poisons*, for they kill by direct action on the body. They are used because sucking insects pierce the skin of the plant and suck the juices from the inside, and would not absorb any arsenic present on the surface.

Even if some insect pest which was unknown to a grower made its appearance in his houses, therefore he should be able to apply the proper spray to control it by observing its feeding methods. If it actually ate the leaves, stems, or fruit, an arsenic spray would be indicated as the best to apply, whereas if it was merely a sucker a nicotine spray would be best to try first. If these methods were not satisfactory the grower would naturally make inquiries as to whether any scientific information was available which would aid in combating the insect in any other way.

Control is not always the simple matter of applying a single spray. The habits of the insect must frequently be taken into account, and treatments be so adjusted as to catch insects at different stages in their life-history. For example, in the treatment for white fly by fumigation, the adult and larval stages are killed but not the eggs, and a second treatment has to be done after from two to four weeks, according to the temperature, to kill adults which hatch from all the eggs present when the first fumigation was done. The details vary, of course, for each pest, and discussions will be made on the individual insect pests in a later issue.

## TOMATO DISEASES AND THEIR CONTROL.

## KEY FOR THE IDENTIFICATION OF DISEASES.

The tomato grower can only identify a disease by the symptoms which diseased plants show. These are usually perfectly definite and characteristic for each disease, and when once a disease is known there is rarely any

difficulty in recognising it again. The illustrations in this bulletin have been made from typical specimens taken from South Australian glasshouses, and should help to render identification easy. The following table of condensed descriptions of symptoms may be of further assistance in tracking down a disease to its proper cause. When the table is being used to identify a disease, if the short descriptions for the symptoms given under the sections "Leaves," "Fruit," &c., appear to agree, the longer description of the disease on the page referred to should be looked up and carefully read. If the trouble still does not seem to fit correctly any of the described diseases, it would be advisable to send a specimen for identification either to the Department of Agriculture or to the Waite Institute.

Troubles caused by insect pests, such as cutworms, stem-borers, &c., have not been included in the Table except in certain cases, such as Eelworms and Brown Surface Mite, where the insect is too small to be seen with the naked eye.

#### A. SEEDLING—

Disease.

1. Constriction of stem at ground level with seedling falling over (Fig. 15) \*Damping-off.
2. Seedling stunted and purplish; roots rotten, brown, and dying back from tips \**Verticillium* wilt or other root-rot.

#### B. WHOLE PLANT—

1. Becomes suddenly stunted, young leaves bronzed diffusely or in spots, or just with faint pallid spots if cold (Figs. 3, 4, 5, 8) Spotted wilt (p. 262)
2. Becomes slightly stunted, with young leaves rolled and with mottled yellow and green areas (Fig. 13) Mosaic (p. 271)
3. Young leaves with blackish collapsed spots or lines on them; small or large dark sunken streaks on stem or leaf stalks (Fig. 11) Streak (p. 269)
4. Top growth spindly, leaves yellowing from below upwards \**Verticillium* wilt or other root-rot.
5. Whole plant wilting in warm part of day (Fig. 17) .. Do.
6. Rank giant growth, no flowers ..... \*Buck plants
7. Shoots going "blind," tufted and swollen at ends (Figs. 31, 32) \*Rosette
8. Rusty bronze discoloration gradually spreading up stem and out on to leaves, which slowly shrivel \*Brown surface mite.
9. Becomes gradually stunted, sometimes sickly yellowish or fruit not setting properly (Figs. 34, 35) \*Eelworms.

---

\* Illustrations and descriptions of disease will appear in a subsequent issue.

## C. LEAVES

## (a) Younger leaves only.

- |                                                                                                                                                               |                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| 1. Distinct bronze discolorations in spots or diffuse or only so faint as to be shiny when turned towards light; occasionally only pallid circles or patches  | Spotted wilt<br>(p. 262) |
| 2. More sharply limited spots with tissue collapsed through to other side and more blackish. In spots or lines. Stem streaks also usually present. (Fig. 11.) | Streak (p. 269)          |
| 3. Young leaves rolling round considerably, hard to spread out flat; and often distinct yellow and green mottling (Fig. 13)                                   | Mosaic (p. 271)          |

## (b) Older leaves also affected.

- |                                                                                                                                    |                                               |
|------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| 1. Small spots less than $\frac{1}{4}$ in., light-brown to ashy in centre with minute black dots in central part of spot (Fig. 21) | *Leaf-spot.                                   |
| 2. Dark spreading spots, often "zoned" (Fig. 23) . . . . .                                                                         | *Early blight.                                |
| 3. Odd leaflets dying first, shrivelling while still green (Fig. 14)                                                               | *Bacterial blight.                            |
| 4. Odd leaflets dying first, due to spread of light-brown diseased patches; sometimes tufts of mould (Fig. 24)                     | * <i>Pleospora</i> leaf blight.               |
| 5. Dark sooty growth on leaflets which will wash off, leaving leaflet with healthy tissue                                          | *Mould following aphid or white fly.          |
| 6. Rusty bronze discoloration spreading over leaves, from stem end. Leaflets gradually shrivelling                                 | *Brown surface mite.                          |
| 7. Bottom leaves yellowing gradually and later dying from margins                                                                  | * <i>Verticillium</i> wilt or other root-rot. |
| 8. Pallid tissue in centre of leaflets (Fig. 30) . . . . .                                                                         | *Pallid leaves.                               |

## D. FRUIT—

- |                                                                                                          |                                |
|----------------------------------------------------------------------------------------------------------|--------------------------------|
| 1. Large circular rotten patch at tip end of fruit (Fig. 28)                                             | *Blossom-end rot               |
| 2. A black rot starting from cracks at stem end (Fig. 27)                                                | * <i>Phoma</i> fruit rot.      |
| 3. Small "birdseye" spots with light centres (Fig. 25) .                                                 | * <i>Pleospora</i> fruit spot. |
| 4. Tough white patch on one side of fruit (Fig. 29) . . . .                                              | *Sunburn.                      |
| 5. Diffuse bronzing over skin of green fruit, which later develops fine network of cracks and scabs      | *Brown surface mite.           |
| 6. Fruit becoming soft and sloppy inside skin. This is a bacterial wet rot usually following grub injury | *See green caterpillars.       |

---

\* Illustrations and descriptions of disease will appear in a subsequent issue.

## E. Roots—

1. Knotty or clubby swellings on the roots (Figs. 34, 35) \*Eelworms
2. Roots dying back from the tips, brownish, with bark easily stripping off central strand of wood. The most usual trouble is *Verticillium* wilt in which the wood becomes browned inside roots and stem; occasionally Black Dot root rot where black specks can be seen in the wood of rotted roots (Fig. 20), less frequently *Pythium* rots in which the roots die back without browning inside the stem \**Verticillium* wilt or other root-rot.

## SPOTTED WILT.

*Description.*—Spotted wilt is most serious as a disease of outdoor tomatoes, but in certain years it has caused a great deal of loss in glasshouse tomatoes, and has necessitated replanting houses even two or three times.

The main symptoms of the disease are bronzing of the younger leaves, with cessation of growth of the plant. The disease is most severe in the seedling stage, and in glasshouse work, in fact, tends to disappear as the weather warms up. (This does not mean that infected plants recover, but that as the season advances and the plants become older further infections gradually cease.)

FIG. 3.—Diseased and healthy plants of Sensation tomato, showing an early stage in the effect of spotted wilt. The diseased plant has ceased growth and has acquired a slightly bunched top with young leaves bent downwards. The young leaves have bronze markings on their upper surface.

If the weather is cold and dull the bronzing characteristic of the disease may be very difficult to detect. Sometimes it can only be seen as a faint shiny appearance on the upper surface of affected leaflets when they are turned towards the light. Under cold conditions plants frequently become only pallid in appearance, with suggestions of yellowish or whitish circular

blotches in the leaves. Bronzing as a symptom is thus most distinct, as a rule, when the plants are growing rapidly, and most indistinct when the plants are not making rapid growth for some reason. It is rarely so definite and distinct on glasshouse plants as it frequently is on outdoor plants.

In all cases, however, affected plants cease growth, and are soon readily picked out by the fact that they are "left behind" by the more rapid growth of neighboring healthy plants (Fig. 3\*). The appearance of the crown of leaves at the growing point of young plants also alters slightly, the leaves usually appearing somewhat stiffer, bent a little more downwards

FIG. 4.—Diseased and healthy tomato plants from the field showing a later stage in the effect of spotted wilt. Bronzing on the upper leaves was severe, and some of the leaflets have shrivelled. Note the marked stunting again.

than usual, and often somewhat bunched owing to the cessation of growth of the stem (Fig. 3). The first slight changes in the normal relations of the leaves at the growing point often enable affected plants in glasshouses to be noticed a day or two before the bronzing becomes definite (Fig. 8). If the plants are left in some days after they become affected they are soon noticeable by their dwarfness and by the fact that the leaves have not the good flat spread of normal plants, the leaflets often being slightly folded inwards. As stated previously, glasshouse plants do not usually continue to become affected after they have reached a height of some 18in. to 2ft. (The reason for this is obscure. It may be that old plants cannot easily be infected, or that the humidity becomes too great for the thrips, or partly, perhaps, that there is masking of symptoms due to higher temperature.)

\*Figures 3-10 are reproduced by permission of the Council for Scientific and Industrial Research from C.S.I.R. Bulletin No. 44, "Investigations on 'Spotted Wilt' of Tomatoes."

Outdoor plants may become affected at any age, and infection may continue right through the summer, though it usually diminishes in intensity after the plants are half grown. The bronzing on the young leaves usually appears suddenly while the plants are in full vigor (Fig. 5). In warm weather it may be very severe, and the affected shoots dry up in a few days, almost as if they had been scorched. The plants then present a rather unsightly appearance (Fig. 4) and produce no further useful growth or fruit during the season.

FIG. 5.—Bronze markings of spotted wilt on the upper surface of a Golden Queen leaf.

The fruit from affected plants may have more or less circular bronze-colored markings while still green (Fig. 6, but not frequent) or variously shaped yellow blotchy areas when ripe (Fig. 7). These blotchy areas on ripe fruit may occur in the most varied patterns, from perfect concentric circles to sharply defined islands of bright red on yellow, or *vice versa*. Fruit from affected plants is not always blotched, however, and blotchy towards also be harvested from plants whose leaves are apparently normal. pallid in a  
chiness does occur it is the virus of spotted wilt which is

**Cause.**—Spotted wilt is caused by a “virus,” or infectious sap which is carried from plant to plant both in the field and in glasshouses in South Australia by a very small insect, a special kind of thrips known as the “black carnation thrips” (scientific name, *Frankliniella insularis*) (Fig. 10). If a thrips has picked up the virus of the disease by feeding on a diseased plant, it may inoculate the disease into any healthy plant upon which it feeds subsequently. It can even inoculate a plant by feeding for only a few hours (possibly less than an hour, although this has not yet been

FIG. 6.—Bronze markings of spotted wilt on a green tomato fruit.

FIG. 7.—Irregular red and yellow blotches on a ripe tomato fruit from a spotted wilt diseased plant.

FIG. 8.—Diseased and healthy Early Dwarf Red seedlings, showing the very slight stunting, with bending downwards of the young leaves and folding together of the leaflets, which is often the only sign of spotted wilt in the earliest stages.

tested). It may then be disturbed perhaps and fly to a second plant, and so on for a life of several weeks. It is easy to see, therefore, how a very few insects in a glasshouse may cause very considerable loss, simply by moving from plant to plant and inoculating the virus of spotted wilt into each plant they feed on.

The virus of spotted wilt, when it is inoculated into a plant by the feeding of infective thrips, takes some 10 to 14 days to develop inside the plant before the top shows the bronzing and stunting symptoms. When diseased plants are noticed, therefore, it is scarcely ever possible to find the insect still on them which inoculated the disease into them. In this time it is almost certain to have moved on and inoculated several other plants. It is often possible, however, by careful examination, to detect the feeding-marks which the insect made. These are usually very inconspicuous, however, and consist only of one or more small sucked-out areas with a few black dots of excreta on them or near them (Fig. 9). They will probably be found on one of the older leaves, for the plant will have made some growth during the 14 days or so incubation period of the disease since the time of inoculation by the thrips.

FIG. 9.—Tomato leaflets showing the small sucked-out areas (a) with black spots of excreta on them, the feeding marks of the black carnation thrips, which spreads tomato spotted wilt. The disease is inoculated into the leaf by infective insects when they feed.

*Life-history of the Black Carnation Thrips, the Insect Carrier of the Spotted Wilt Virus.*—Since it is the black carnation thrips which is responsible for spreading the virus of spotted wilt, it is advisable to know as much as possible of the habits of this insect with a view to checking the thrips, if possible.

The thrips itself is a small, neat, black insect, about  $1/12$ th inch. long, which can move by quick hops or by short flights. It never becomes very abundant on tomatoes, and is usually very difficult to find, even when spotted wilt is spreading rapidly in the glasshouse.

The eggs are laid by the female in the leaf-tissue near where she feeds, being pushed just underneath the skin of the leaf. A female may lay from one to as many as eight eggs per day, the average number being three or four.

After some 10 days (more or less according to whether the temperature is low or high), the eggs hatch, and very small larvæ struggle free and begin to feed on the tissues of the leaf. At first they are scarcely visible, but gradually grow until they have the appearance of a very small yellow or orange-colored grub about half the size of a pin's head.

When full fed they go down to the soil for the pupa stage, in which they gradually change into a fully formed adult with wings (Fig. 10).

On emergence from the soil as adults they again seek plants to feed upon. If the plant on which they were hatched and spent their larval life was one infected with spotted wilt, the larvæ will have picked up the virus of the disease in feeding, and the adults will also be infective and capable of inoculating the disease into any further healthy plants they feed upon. The adults may live from one to several months. Females can lay eggs which will develop normally without having been fertilised by males.

FIG. 10.—A black carnation thrips (*Frankliniella insularis*), the insect which spread tomato spotted wilt. Magnified 50 times.

**Control.**—No way has yet been discovered of killing a virus after it has been inoculated into a plant, so that all efforts towards the control of spotted wilt at present must be directed to preventing the inoculation of the plants by infective thrips.

The first question which the glasshouse grower will ask is, "How do the thrips get in to the glasshouse? Where do they come from?" Unfortunately, the black carnation thrips, which carries the spotted wilt virus, is a very widely distributed thrips, and occurs in numerous garden flowers and weeds, especially in summer and autumn. There is no proof yet, however, that they do actually fly into glasshouses, though the occurrence of the first spotted wilt affected plants near the doors in many cases would seem to suggest that they sometimes do get in through the doors or broken panes at the ends.

In other cases, however, proof has been obtained that they are carried in from the seedbeds when the young seedlings are planted out, and this is probably the most frequent way of their gaining entrance. Not only may the adults be carried in, but also eggs still unhatched in the leaf, or larva feeding on the leaves, or even pupæ in the soil round the roots. It is, therefore advisable to keep a sharp look-out right from the commencement for traces of thrips feeding-marks on the seedlings in the seedbeds. Something can be done to check the insects, if they appear, by picking off leaflets with feeding-marks on them and spraying or dusting the plants thoroughly with nicotine. Probably, however, it would be more satisfactory to see that the seedbeds are kept free of weeds when they are empty, that weeds do not grow close round them at any time, to use specially prepared soil for the seedbeds as described on page 158 (September issue), to place the seedframes as far as possible from garden flowers, and to see that the sides and covers of the frames are reasonably tight. Cases have been recorded where new glasshouses or seedframes erected on new land have had more spotted wilt in them than old houses. The explanation is probably that the insect carrying the disease was present in the weeds on the virgin land.

Not all individuals of the black carnation thrips carry the virus of spotted wilt. They must first have picked up the virus of the disease by feeding on an infected tomato plant or an infected weed. Cases have been seen where thrips and their feeding-marks were present in a glasshouse and no spotted wilt was there. It is as well to be on the safe side, however, and make an effort to check thrips right from the early seedbed stage.

The next question to be considered is, "Can anything be done once infected thrips have gained entrance to a glasshouse and are already spreading the spotted wilt?" Very little success has been obtained in the few experiments carried out so far where spotted wilt had already infected a quarter or more of the plants when the experiments commenced. Matters, however, should never be allowed to develop so far, for at such a stage it is not only the quarter already showing the disease, but possibly a still larger number which have already been inoculated and which are still in the incubation period, which are actually infected. Leaving infected plants in also considerably increases the chances for the multiplication of infective thrips. If the recommendations on pages 161-2 (September issue) for the regular removal and burial of diseased plants at the end of every day are carried out this must necessarily considerably reduce the chances for multiplication of the disease. The difficulty is, however, that because of the long incubation period of the disease one can never "catch up," so to speak, and get rid of all actually infected plants at once.

The value of spraying or dusting as an aid in the control of the disease also requires further investigation. A comparatively few thrips, half the size of a pin's head, can cause losses running into hundreds of plants in a glasshouse. Spraying would have to be extremely thorough to get these few thrips, and eggs in the leaves and pupae in the soil are out of reach of sprays. Since nicotine sprays are known to kill thrips, however, it is worth doing until further experimental work has devised a better method. At least two sprayings at an interval of 10 days should be given, using a nicotine-soap spray or a nicotine dust. If dust is used the temperature should be at least above 76°, and the warmer the better.

Summarising control methods for spotted wilt in glasshouses:—

- (1) Keep seedframes free from weeds during the time when they are not in use, and no weeds growing near them.
- (2) Use a special soil for seedframes which has not had weeds growing on it for a year.
- (3) Keep a careful watch on the seedlings in the seedbeds for signs of thrips feeding-marks. If noticed, pick off leaflets which have been fed upon and spray with nicotine-soap mixture.
- (4) Remove and bury infected plants from the glasshouses every day and spray twice with strong nicotine-soap spray at an interval of 10 days. Nicotine dust may be used if the temperature is 80° or more.

The control of spotted wilt in outdoor crops is at present still more difficult than glasshouse control. There is no direct method, such as spraying or dusting, which can be recommended as sufficient in itself. Tomatoes grown out in the country, well away from flower gardens, suffer much less from spotted wilt than those near the city, probably because the carrier thrips is not so abundant. Rotation of crops, so that tomatoes are not grown on land which has had tomatoes or potatoes the year before, is of value. Good cultivation of the soil before the tomatoes are planted and the keeping down of unnecessary weeds round the patch also assist. Particular attention should be given to getting out weeds of the same family as tomato, such as black nightshade. Finally, it is advisable to go through periodically (as frequently as possible) and pull out and destroy infected plants, especially in the young stages. These plants never do any good, and serve as centres from which infection can spread to healthy neighbors. The evidence at present available points to these indirect methods being of more value in control than direct spraying or dusting. Under certain conditions a nicotine-containing spray or dust may do some good.

#### STREAK DISEASE.

*Description.*—Streak disease (sometimes called stripe disease) may cause black stripes running up the stem of a plant, irregular black spots and lines on the younger leaves (Fig. 11), and sunken, discolored pits on the fruit (Fig. 12). In young plants it is usually only the markings on the leaves which are noticeable, though small, sunken streaks may also occur on the stem. At this stage it is sometimes very difficult to distinguish from spotted wilt. On older plants, however, the symptoms become more characteristic and easy to distinguish from spotted wilt. The stripes up the stem sometimes run for long distances and may be  $\frac{1}{2}$  in. or more in width, the tissue being sunken and grey-brown to black. The marks on the leaves are distinct from those of spotted wilt in that they are never a bronzing on the surface of the leaf in the early stages, but the tissue collapses right through and the marks can be seen on both sides of the leaf. They are also very definite and sharply marked spots or lines, and do not have the diffuseness so characteristic of spotted wilt. The color is also darker, being black in tint instead of the bronzing of spotted wilt. In many cases the leaf markings occur as irregular lines running more or less parallel to the midrib or main vein (Fig. 11), though leaves with

merely small, scattered, collapsed spots are also common. The fruit markings, sunken, irregular in shape, and discolored brownish are very characteristic.

FIG. 11.—Tomato streak disease on the leaves, showing the black sunken markings visible from both sides.

FIG. 12.—Tomato streak disease on the fruit, showing the characteristic brownish, sunken markings.

Very frequently infected plants are found to be several all together in a row, and the explanation of these cases is probably that the infection was carried on the fingers from one plant to the next during pruning.

*Cause.*—Streak disease is caused by a "virus" or infective sap, which may be carried from plant to plant directly on the fingers, or by green aphids. Like other virus diseases it has an incubation period of some 10 to 14 days, more or less, from the time of inoculation until the time when it is first visible as blackish spots and streaks on the younger leaves. During this time the amount of virus, which was probably extremely small when it was inoculated, has been multiplying within the plant until by the time symptoms show the whole plant is full of the infectious virus.

In North America streak disease is considered to be due to a mixture of two viruses (tomato mosaic and potato mosaic). The symptoms of streak disease in South Australia differ somewhat from those in North America, and so we cannot yet conclude that the same explanation of the cause holds here. We also have no information as yet on how the disease lasts over from season to season. It appears to be entirely a glasshouse disease here, and is not met with in the outdoor crops.

*Control.*—The most common way of spreading streak disease in glass-houses appears to be on the fingers of pruners. The small amount of sap which may get on the fingers from pruning a diseased plant (even though it may not yet be showing symptoms of the disease) seems to be sufficient to carry the disease on to the next healthy plant pruned. Here again the recommendations on pages 161-2 (September issue) for frequent inspection, marking, and removing of diseased plants *at the end of the day*, would probably assist greatly in the control of streak disease. In addition, the leaving of pruning for a fortnight if streak plants are seen is advisable, so that all infected plants have the opportunity to show up before pruning could spread the virus from plant to plant.

Aphis should also be kept under control with nicotine-soap spray or nicotine dust.

A curious feature of streak disease is that it is considerably influenced by the manurial treatment. Nitrogenous manures, and especially nitrate of soda, make it worse, whereas sulphate of potash tends to check it. The balanced manure suggested on page 163 (September issue) will tend to keep the disease in check, but if an outbreak does occur at a late stage when plants are too big to pull out, potash can be applied at a rate as heavy as 40lbs. per 100ft. of house, and will help considerably in firming up the fruit and reducing the amount of pitted fruit.

#### MOSAIC DISEASE.

*Description.*—Mosaic disease is not always easy to detect, and yet at times it may be extremely pronounced. It may show as an indefinite mottling of the leaves, in which light green and dark green areas occur together. Very often the leaves have a puckered appearance owing to the light green and dark green areas growing at different rates, so that the leaf cannot be spread out flat. Under glasshouse conditions there is usually considerable rolling inwards of the margins of the leaves (see Fig. 13). Also, under some conditions there may be very considerable distortion of the leaf-blades, which may occur to such an extent that some of the leaf-blades may not develop at all, there being only thin thread-like midveins, a stage which has been named "fern-leaf," or "stringy-leaf." The mottling due to mosaic should not be confused with that of the pallid leaves to be illustrated in Fig. 30. Mosaic mottling is a mottling of light green and dark green areas, and does not become whitish and pallid; it is nearly always accompanied by leaf-rolling, twisting, or distortion.

In its milder forms it is sometimes very difficult to detect whether a plant is infected with mosaic or not, although if the young plants are growing vigorously there is usually not much difficulty. In the later stages of growth the effect may vary from a very small to quite a considerable reduction in yield of fruit, due mainly to non-setting of the blossoms. What fruit there is, however, is usually normal in appearance.

*Cause.*—Mosaic is due to another “virus,” or infective sap. It is extremely infectious, and the small amount which adheres to the fingers or pruning knife after pruning a diseased plant may be quite sufficient to inoculate several healthy plants pruned subsequently. In some cases, in fact, merely brushing against a diseased plant and then brushing against a healthy one may be sufficient to inoculate the latter. Once again, although an exceedingly small amount of virus is sufficient to transmit the disease, it soon multiplies in an infected plant, which in a few days becomes full of virus in every part.

FIG. 13.—Mosaic disease on a young glasshouse plant, showing the rolling round of the leaflets, with tendency towards thready leaflets shown at (a).

Aphis, after sucking a diseased plant, can also transmit the disease subsequently to any healthy plants on which they feed.

*Control.*—The routine of inspection, marking, and removal of diseased plants at the end of every day or two, as previously recommended, will be of great assistance in preventing the spread of mosaic disease. If several cases appear it would be advisable to prune only once a fortnight, so as to avoid spreading the virus from plants which are still in the incubation period. It would also be safer to mark doubtful plants and prune them at the end of the day.

All plants removed should be buried or burnt, for the virus of mosaic disease is very long lived, and may last in well-rotted compost heaps for several years. It is not always easy to say where the first infection every season comes from. The keeping of seedbeds free from weeds while they are not in use will most probably aid in reducing the chance of these first infections. Aphis should be controlled by nicotine sprays or dusts.

[To be continued.]

# THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

## FORTY-FIRST ANNUAL CONGRESS.

In the presence of a record attendance of delegates and visitors the Forty-first Annual Congress of the Agricultural Bureau of South Australia was opened in the Way Hall on Monday, September 15th, 1930, at 8 p.m., by His Excellency the Governor, Brigadier-General the Hon. Sir Alexander Hore-Ruthven, V.C., K.C.M.G., C.B., D.S.O.

Officers present at the opening ceremony included the Hon. S. R. Whitford, M.L.C. (Minister of Agriculture); Messrs. F. Coleman (Chairman); H. N. Wicks (Vice-Chairman); A. M. Dawkins; Geo. Jeffrey; J. W. Sandford; R. H. Martin; A. J. Cooke; S. Shepherd; A. L. McEwin; P. H. Jones; Professor A. J. Perkins (Director of Agriculture); W. R. Birks (Principal, Roseworthy Agricultural College); members, Advisory Board of Agriculture; Messrs. W. J. Spafford (Deputy Director of Agriculture); Geo. Quinn (Chief Horticultural Instructor); C. F. Anderson (Acting Poultry Expert); W. J. Adey (Director of Education); Professor J. Prescott and Dr. J. Davidson (Waite Research Institute); other officers of the Department of Agriculture; H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary, Agricultural Bureau).

The following delegates attended:—Alawoona—W. Paull; Allandale East—W. M. Laslett; Alma—A. B. Smyth, A. H. Shepherd; Angaston—Wm. Sibley, Wm. Patching; Arthurton—H. D. Noble, L. Gordon; Auburn Women's—Miss L. Dennison, Mrs. J. F. Schmerl; Ballhannah—C. Grasby, H. Rollbush; Balaklava—H. B. Schaefer, H. Masters; Beetaloo Valley—H. K. Paul, T. Jones; Belalie North—W. Cummings (jun.); Belalie Women's—Mrs. Alec Mitchell, Mrs. E. L. Orchard; Berri—A. G. Jarvis, A. V. Mills; Blackheath—H. Paech; Black Springs—C. Dunn, A. Heinrich; Blackwood—F. B. James, H. Goldsack; Block E—M. Pethück, A. R. Nenke; Blyth—W. O. Elme, H. E. Zwecke; Booleroo Centre—S. McMahon; Boolgun—W. A. Ellis, R. Castle; Borrika—E. H. Huxtable, V. V. Brown; Bowhill—A. S. Just, A. P. Spry; Brinkley—E. G. Humphrey, C. H. Pearson; Brinkworth—G. E. Ottens, H. Snow; Brownlow—G. H. Roocke, F. Woithe; Buchanan—L. V. Bell; Bute—E. Ebsary; Bugle—H. Ballman, E. T. Smith; Butler—D. B. Butler; Calca—Pat. Murphy, Ed. Roberts; Caliph—G. H. Trevilyan, W. H. Todd; Caltowie—J. E. Lehmann, R. W. Wilkinson; Caradue—E. T. Marshall; Chandada—R. Loveday, C. Wheaton; Cherry Gardens—C. G. Terrell, I. N. Stone; Clanfield—H. L. Billing; Clare—J. Scales, H. F. Hicks; Clarendon—L. C. Spencer, T. B. Brooks; Coomandook—F. E. Ballard, W. R. Trestrail; Coonawarra—Wm. Snelling; Copeville—J. N. #### OPENING CEREMONY.

In the course of the opening address, His Excellency said he supposed there had never been a time in the history of the country when the importance of bringing the aid of science to agriculture had been greater. The one subject occupying their minds was how to reduce the cost of production, especially in the export industries. One certain method was by reducing the cost of the production of wheat, wool, and meat by eliminating the pests that destroyed and hampered the growth of those valuable commodities. They were all anxious to improve and increase trade within the British Empire, and that could

only be effected if they could compete in British markets with other countries. It was staggering to find that one-tenth of what the country received for its wool last year went to balance the loss inflicted by blowfly and footrot. Such figures revealed how large a margin might be saved, and how immediately closely connected was the work of scientific research in the cause of Empire development. Australia might well be the stock farm of the Empire, supplying cheap meat to all those parts less well situated.

#### DISSEMINATION OF KNOWLEDGE.

Not only was the lowering of production costs a question of overcoming pests and diseases; there was also a huge field of positive health work in agriculture, in breeding better animals for fleece, hide, or meat; introducing new fodder plants, improving cultivation of grain and fruit, and basing settlement schemes on fuller knowledge of the properties of the soil. But in order to get the best results co-operation between the scientist in the laboratory and the man on the land was essential. Although he had found among farmers and agriculturists a considerable amount of interest, he regretted that occasionally he found a good deal of ignorance as to what the scientists were doing. The great task now was to disseminate the knowledge gained. Co-operation was also needed between the different institutions and scientists throughout the Empire, so that no time and money should be spent in covering ground for which results were already in existence elsewhere.

At the instance of Mr. G. Jeffrey, seconded by Mr. R. H. Martin, a hearty vote of thanks was accorded His Excellency for opening the Congress.

#### THE MINISTER'S ADDRESS.

Addressing the Congress, the Hon. S. R. Whitford, M.L.C. (Minister of Agriculture) said:—"It is with pleasure that I find myself called upon to-night to address this great body of organised primary producers. I am, as you are no doubt aware, comparatively new to office, and fear that my Parliamentary and administrative duties have not hitherto allowed me to come into as close contact with you as I could have wished. I am persuaded that you will find me to improve upon closer acquaintance, and I trust that, in due course, time will remedy this apparent shortcoming of mine. I am reminded, however, that in the eyes of some this may not be my only shortcoming; it may be objected that I am Minister of Agriculture without any personal knowledge of agricultural operations. But, just because I am unfortunate enough not to have been a farmer of sorts, you must not imagine for a moment that my interest in rural production is lukewarm. Indeed, I shall go as far as to say that here in South Australia nobody is adequately fitted to hold a prominent position in public life who is not intensely conscious of the importance of rural production both to himself as an individual and to the State as a whole. Moreover, am I not surrounded by a competent technical staff, upon whose advice I can always depend when trouble looms ahead? As for myself, what I lack in knowledge and experience in these matters, I promise to make good in helpful sympathy with all those who in these difficult times are carrying the burden of rural production; nor, I trust, shall I be appealed to in vain by those to whom I can be of any Ministerial assistance.

But, on consideration, I think that layman though I be in matters agricultural, I can claim two points of contact with you, which should assist towards our mutual understanding. I have been a miner, and therefore a primary producer; and whilst your days might be said to be usefully occupied in tickling the surface of the earth, mine, in earlier times, took me into its bowels in quest of a livelihood. I entertain no doubts as to which of these occupations is the pleasanter of the two; but whilst I might be in two minds as to which is the more honorable, I am personally convinced—and I am sure that you will agree with me—that there is no other occupation more honorable or more useful to mankind than either of these two..

My second point of contact lies in the fact that, whilst I can look upon you collectively as an organisation for that type of mutual assistance that comes from the free exchange of experience and ideas, I, on my part, have been an organiser of industrial bodies for mutual help and economic defence. These facts, I take it, will help me to visualise your efforts and your troubles with the sympathy of complete understanding. It is often said of rural producers that relative isolation, coupled with incessant struggle against intangible forces, tend to make them unrepented individualists, whom a superhuman smith alone could weld into mutually helpful association. Your corporate existence of over 42 years would seem to give the lie to any such suggestion; but perhaps I should attribute your success in this direction to the rigid exclusion of political and religious topics from the ambit of your activities. I am told that you have 300 Branches distributed over the length and breadth of the State, aggregating 8,200 members, and I realise very fully that your claim to speak on behalf of the rural community as a whole is based upon quite adequate competency. I am particularly pleased to learn that the ladies have not been overlooked, and that you have 18 women's Branches, eight of which have been opened in the present year. In no other occupation is woman to a greater extent the active working partner of man than in rural industries, and in no other, I fear, has she, as a rule, less opportunity for personal development and relaxation. Hence, I trust that these women's Branches will do much towards raising the status and improving the outlook of country womenfolk. The only fault I have to find is that 18 Branches out of a total of 300 seems to me an altogether disproportionate number. There should, in my opinion, be as many women's Branches as there are men's.

I may be expected to say something about the agricultural policy of the Government to which I have the honor to belong. I shall remind you, however, that we are going through troublous times of world-wide incidence, and that since our assumption of office the financial outlook has unavoidably and inevitably overshadowed every other issue. Nevertheless, I do not wish to imply that this Government, any more than any other Government worthy of the name, can afford to overlook the national claims of rural production; indeed, had there been any need, the financial crisis through which we are passing would have sufficed to make the position clear. Our debts—incurred very largely apart from war commitments in the development of a new country—can be met from one source only, namely, the primary products of the country. The present Government is well aware of this position and to the limit of its means is anxious to foster rural production in the general interests of the State. Many of you, I know, have been putting up a gallant fight against adverse seasons and falling market prices, and I can realise how much at times your patience must have been tried by these insistent demands for greater and greater production. Unfortunately, as a community, we find ourselves to-day in an exceedingly difficult position, partly, it must be owned, of our own creation; and, whilst we need entertain no doubts as to eventual extrication, there appear, humanly speaking, to be two things only that can open the way to an early return of normal conditions, namely (1) strictest economy in both personal and national affairs, and (2) highest possible returns from primary production. In the circumstances, therefore, whilst realising that the value of returns is dependent partly upon market prices, I feel that I, too, must add my voice to those of others who have already asked you, on behalf of the State, to aim persistently at maximum production from your holdings, particularly in the matter of products enjoying a ready demand on the markets of the world, such as wheat, wool, fat lambs, eggs, and dairy produce generally. On the part of all, a policy of this kind will imply intensified effort, on the part of some possibly unrewarded sacrifices, but to the majority, I am satisfied, it will bring consolidation of interests and ultimate prosperity. But, in these days, I feel sure you will rise above mere personal considerations and feel nothing but pride in the fact that you—a relatively small section of the community—hold in your hands the key which is to open the door to the return of better days for the State which has entrusted to you the management of its lands.

Whilst on the subject of exports, let me remind you that if in the past one factor within our control more than any other has detracted from their net value, both to the exporters concerned and to the State as a whole, it has been unevenness in quality, coupled with slovenly get-up and faulty grading. This is a very serious matter to all concerned, and I trust that when you aim at maximum production you will also, if only in your own interests, aim at optimum quality that your circumstances permit of. The world does not want addled eggs or butter made from inferior cream, nor does it buy chaff and rubbish when purchasing wheat; it follows the simple expedient of paying less for the article than it would otherwise have done. Let me remind you, too, that on any market the inferior article sets the standard of price, much to the detriment of the interests of the State. There is no reason why New Zealand butter and lambs should command higher prices on the markets of the world than our own, apart from the piebald character of many of our consignments.

How such a policy of expansion can be developed to best advantage I lack perhaps the competence to say, and, having indicated its necessity, I must leave the difficulties and practical details to yourselves and my officers, whose efforts in this direction will at all times have the support of Government. It is true that I have been told that wheat at 3s. 6d. a bushel will not pay costs of production on a 6½bush. harvest such as was garnered in last season, but with the return of good seasons, which we all anticipate, would this be true of a normal 12bush. harvest? And with the general extension of improved farming methods, may we not hope that the day is not far distant when again, like in 1916, we shall reap a 16½bush. harvest.

I have already admitted lack of experience in matters agricultural. I therefore crave your indulgence for anything that might be amiss in a little flight of fancy of mine as to the position of the farmer. In these days I conceive of him as occupying a relatively privileged position, as one upon whom has fallen the duty of rescuing more or less helpless fellow citizens. I conceive of him as very largely master of his own

destiny, secure in his home tenure, master of land, which is both workshop and larder, begetting his own working staff, whose family is not called upon to scour the highways and byways in quest of that illusive will-o'-the-wisp—work.

I conceive of the farmer as director of an important national concern, whose duty it is to so arrange matters that the land he occupies provides regular daily work for himself and his staff. And in such circumstances I cannot imagine him excluding everything from his holding except wheat; although I admit that human nature being what it is, the glamor of 5s. or 6s. for wheat in the field would probably drown the voice of conscience in this respect. But to-day wheat is nearer 3s. than 5s., and in the national interest must still be grown by those to whom the land has been entrusted, and when, unfortunately, individuals fail here and there, there are always others ready to step into the breach and continue the good fight. When the market value of the main crop is low, I can imagine the farmer, consciously or subconsciously, determining that his land shall do more than carry wheat, that he and his staff shall make more intensive use of the daylight hours, that not wheat only, but wool, lambs, cream, pigs, eggs, &c., shall be taken to market, and so maintain at a maximum level the gross returns of his farm.

I trust that my conception of the farmer may not be considered too fanciful. I suggest that what I have in mind is already being practised by many, and hope that those that lag in the rear will join hands with the front ranks and help to hasten on the day when the workless of the community will no longer have to beg for work in vain.

I have already referred to the present essentialness of economy in both personal and national affairs. In this connection the Government of the day has already set its hand to the plough, and there will be no looking back, and private individuals in their own concerns cannot hope to do otherwise. In those delusive years that followed the war we have, both individually and nationally, indulged in an orgy of extravagance; there have been too many motor cars, too many tractors, too much foreign petrol used, too many picture shows, wireless sets, silk clothing &c.; in fact, too much mortgaging of the future; and the net result is now obvious to the most near-sighted among us. Let us strive to return to the simpler ways of the past, and all will eventually be well with us." Mr. S. Shepherd moved, and Mr. A. L. McEwin seconded, a vote of thanks to Hon. S. R. Whitford, M.L.C.

#### CHAIRMAN'S ADDRESS.

Mr. F. Coleman (Chairman of the Advisory Board of Agriculture) said:—

The hearty applause with which you expressed your appreciation just now of His Excellency's address meant something more than thanks for his presence at the opening of the Forty-first Congress of the Agricultural Bureau. Might it not also be taken as a recognition by this gathering of primary producers of the State of the real, practical interest and encouragement His Excellency and Lady Hore-Ruthven have shown at all times in the development of South Australia and the welfare of the people generally? His phrase, "Hats off to the past, coats off to the future," has behind it a strong incentive to bear our burdens as the pioneers bore them, and by hard work to do our share, each and everyone, to help our State in this time of need.

We welcome among us the presence of the Hon. Minister of Agriculture, and assure him that the vote of thanks just accorded him was no formal one, but an appreciation on behalf of the primary producers of the honest efforts being made by the Government to meet our financial liabilities and put our house in order.

The only change in the personnel of the Advisory Board has been the resignation of Mr. Mayfield, of Booborowie (on account of ill health), and the appointment of Mr. A. L. McEwin, a practical and successful farmer of Blyth, to fill the vacancy caused by the resignation of Mr. W. S. Kelly in the previous year.

I think it may be taken for granted that there is need for more agricultural co-operation among us, and especially among the smaller producers, many of whom are often poor because of backward methods, and backward in their methods because they are poor. Surely the purpose of the Agricultural Bureau is based on the co-operative lines of mutual help and assistance, on the dissemination of knowledge, and the intelligent application of that knowledge among the agricultural and producing population of the State; the more the Agricultural Bureau functions up to that ideal, the more it endeavors to make the tillers of the soil more efficient members of the community, so will it be worthy of the practical support of every citizen of the State.

We have 300 Branches, an advance of 25 since last Congress, a membership roll of 8,200, and Branches are, as a whole, active and useful, the increase in the number of young men is a most promising sign.

In the first year of the Bureau's existence there were 18 Branches, with a membership of 100. In the course of 20 years the roll increased to 113 Branches, with a membership of 2,000. Twenty years later (1929) the roll further increased to 275 Branches, with a membership of 7,600. A very satisfactory feature of the progress is seen in the membership roll of the past few years. In 1929 net increases to the membership totalled exactly 1,000. At no time during the existence of the Institution has this increase been equalled, and it therefore constitutes a record. During the year just concluded no fewer than 590 members have been added to the previous year's membership, and prior to the record year of 1929 this has only been equalled in one year, namely, 1914. We are indeed very proud of these figures, but I venture to say that there are many districts in this State where Bureaux should be established, and I feel sure that, with the influence of our esteemed Departmental Instructors, we will eventually see Branches studded on the map wherever agricultural pursuits of any kind are practised.

Here I want to say a word of acknowledgment on behalf of the Board and of this Institution as a whole, of the valuable services to the Primary Producers of this State rendered by the Department of Agriculture, so well equipped and organised under the direction of Professor Perkins and his efficient staff.

#### WOMEN'S BRANCHES.

The good attendance at the fourteen Conferences held during the past year has been very encouraging. The attendance of the ladies at these Conferences has now become quite a recognised feature, and sessions in which they have read and discussed papers of special interest have added to the value of these Conferences. There are now 19 Women's Branches, with a membership of 500. These meetings of our Country Women are appreciated by the members, for there are so many matters connected with domestic life, health, sanitation, the garden, and the home generally that will appeal to our women folk.

I would like to publicly acknowledge the assistance which the Director of Education has given us in the work of the Women's Branches. The lectures and demonstrations already given by Miss Campbell have been highly appreciated, and we look forward to a continuance of these lectures, which I can assure the Director will in future be regarded as an important factor in the education of country women. We are indebted to the Director also for the inclusion of Miss Campbell on the Congress Agenda, as well as for his assistance in securing the services of Miss Allen.

#### LIFE MEMBERSHIP OF THE BUREAU.

Life membership certificates have been issued to the following:—Geo. H. Bammann, Roseworthy; W. T. Vigar, Mount Pleasant; A. D. Adamson, Penola; S. Ockley, Penola; A. Fisher, Tatiara; J. B. E. Wake, Kelly; T. Longbottom, Riverton; R. J. James, Riverton; J. B. Kelly, Riverton; A. Langeludecke, Naracoorte; F. Nottage, Meadows; H. G. Kupke, Morchard; B. S. McCallum, Morchard; C. F. Jericho, Butler; D. B. Butler, Butler; A. Bradley, Kybybolite; E. H. Hall, Eureka; W. J. Oldland, Mount Remarkable; H. W. Lawes, Lyndoch; P. D. Burge, Lyndoch; B. F. Hillier, Gawler River; J. H. Bussenschutt, Paskeville; E. Moss, Salisbury; W. J. McNicol, Salisbury; C. G. Borgas, Appila-Yarrowie; J. Sinclair, Green Patch; H. Thompson, Koppio; T. H. Howlett, Artherton; W. N. Seeker, Lucindale; H. E. Harper, Clarendon; L. C. Spencer, Clarendon; E. A. Harper, Clarendon; J. R. Nicolle, Clarendon; W. R. Lewis, Berri; T. F. Orrock, Wepowie; C. H. W. Knauerhase, Wepowie; J. S. Hammat, Lyndoch; R. J. Rose, Laura; S. V. Wake, Elbow Hill.

The Board has considered the appointment of life membership. In the past, a record of 20 years' service as a member of the Bureau has been recognised as qualification for life membership, but as the Bureau gets older and an increasing number of our younger members join, we may soon find that life membership is no longer much more than simply a recognition of 20 years' connection with the Bureau. It has been suggested that these certificates should be granted for distinguished service apart altogether from the fact that the holder may or may not have been a member of the Bureau extending over a period of at least 20 years. In this way the certificates of life membership would apply to those who have served the community through the Agricultural Bureau in a manner deserving of special recognition and for more than simply a membership of 20 years, creditable as that alone is.

#### PRIMARY PRODUCTION.

With regard to our primary products. First, the market for our wool, which a year ago was giving very grave concern, has apparently reached a level not too low to be remunerative. May not pasture improvement (in which the Waite Research Institute is doing such good work), the growing of catch crops on stubbles, and the topdressing of our grass lands, help us to grow more wool per sheep per acre within the agricultural areas in which quite a substantial percentage of our wool, even our Merino wool is grown.

The wheat crop promises well; if Sir Otto Niemeyer is right in saying we cannot look for improving wheat prices, then the only alternative is to increase our production per acre, and I feel sure this can be done by raising the present district average yield to somewhere near that reached by the farmers in each district who get better yields than their neighbors, in short, by speeding up to the standard set by those who year after year raise the heavier crops of grain per acre, and thus not only increase the State's aggregate yield, but reduce the cost per bushel at the same time.

Dairying claims the greater attention, here "many mickles make a muckle." In 1929 we imported into South Australia 1,697 tons of butter, and during the six months ended June 30th last 1,370 tons, these, at £175 per ton, came in 1929 to £296,983 15s., and in 1930 to June 30th £239,820. In round figures nearly £300,000 last year and £240,000 to June 30th this year. Figures which, I venture to say, are no credit, nay,

## **TOP BRAND FERTILIZER APPEAL.**

I came from the depths of the earth, from the waters of the sea, from the atmosphere we breathe. My sources are worldwide.

I offer myself as a servant of the Primary Producer, and, in the end, I am free—I pay for myself several times over.

I feed the plants, increase the yield, lower cost of production, make labour more profitable, and release land needed for other purposes.

I make two blades to grow where one grew before, providing feed and food where hunger would prevail. I make possible profit where otherwise loss would accrue. And, while I serve, I leave with the soil a portion of myself which forms a residual asset for years to come.

Plants, like all other forms of life, must feed. It is my function to furnish food for plant life.

I am a service. All I need is an opportunity to show what I can do. Experiment stations throughout the land have given me this opportunity—have tried me out and found my ability not wanting. Farmers everywhere testify to my power.

I am the farmer's friend and mankind's benefactor.

I am "TOP BRAND SUPER."

are a disgrace to South Australian men on the land. Cannot we do something to stop this drain of over a quarter of a million of money going out of this State to buy our butter? At Eudunda, with 17½ in. rainfall, and without natural advantages beyond dozens of other places in the Lower North among the Barossa and Mount Lofty Hills, some farmers are not only producing butter far beyond their own requirements, but are actually making a living from their cows alone.

Our fruit growers claim our sympathy, our apple growers in particular have had a very disheartening time; just how we are going to help them I hardly know. It has been said that if everyone ate an apple a day we could find a local market for all we produce, but I fear the transportation and handling charges would make the cost too heavy per family in many cases. Fruit juice drinks are helping our orange growers, and surely we could consume far more dried fruits than we do.

Our minor farm products, calves, lambs, pigs, bacon, poultry, eggs, and honey will all, when produced on the farm, help to keep down the household expenses, and often bring in that ready cash so welcome to us all.

#### WOMEN'S BRANCHES.

On Tuesday, September 16th, at 9.30 a.m., Mr. H. C. Pritchard (General Secretary, Advisory Board of Agriculture) opened the sessions of the Women's Branches of the Agricultural Bureau of South Australia, when Mrs. Hammat (Williamstown Branch) was appointed President, and Mrs. Orchard (Belalie Branch) Secretary.

Mrs. H. L. Billing (Wilkawatt) then read a paper, "The Commonsense Kitchen, the Centre of the Home," which was followed by a short paper on "Floor Polishing," by Mrs. Messenger (Kalangadoo).

Short addresses were delivered by Messrs. Geo. Jeffery and A. M. Dawkins. (members of the Advisory Board of Agriculture).

Mrs. Vaughan spoke for a few minutes, and asked for the country women's help in finding positions for children leaving High School.

Miss Lois Allen, B.A., delivered a most interesting and instructive address, "The Differences in Temperament and Ability in Children."

The President of the Metropolitan Branch of the Country Women's Association offered the use of the Country Women's Association rest room at Cravens, Rundle Street, to the delegates during Show week, and spoke on the work in Adelaide of the Country Women's Association.

The Tuesday afternoon session opened at 2.15 with a paper, "Home Nursing," by Mrs. W. Varcoe (Millicent).

Mr. Pritchard answered several questions *re* visits from officers of the Education Department.

Mrs. C. H. Phillis (Parilla Well) then read a paper, "Preparation and Curing of Bacon." On a question from Gladstone Branch several delegates gave suggestions for Annual Meetings, and the work of Branches was discussed. Delegates then visited the South Australian Farmers' Co-operative Union butter factory and egg-packing plant at Mile End.

At the opening of the Wednesday morning session Mrs. Wilson (Wasleys) moved a resolution:—"That the President and Secretary of the 1930 Congress confer with the General Secretary *re* the agenda for 1931 Congress." Seconded by Mrs. Rowe (Williamstown) and carried."

Miss Ellie Campbell, Dip. Dom. Econ., gave an address on "Diets in the Home."

A hearty vote of thanks was accorded the President and Secretary at the conclusion of the morning session, and Mrs. Hammat responded on behalf of herself and Mrs. Orchard. Forty-seven delegates then inspected Messrs. Ellis Bros.' bakeries, Gouger Street.

*The papers read will be published in a subsequent issue of the Journal.*

(To be continued.)

## THE OCCURRENCE OF THE RED LEGGED EARTH MITE (*Penthaleus destructor*, JACK) IN SOUTH AUSTRALIA.

[WORSLEY C. JOHNSON, R.D.A. (Hon.).]

In the Council for Scientific and Industrial Research, *Quarterly Journals*, Vol II., December, 1929, p. 244, and Vol. III., August, 1930, p. 189, there appear paragraphs issuing warnings as to the potential danger of the spread to the Eastern States of this mite (*Penthaleus destructor*, Jack).

The mite is well known in Western Australia, where it is regarded as one of the most serious entomological pests with which the agriculturalist has to deal. It is believed that the pest was introduced from South Africa, and was first reported from Bunbury, in 1917, when it was investigated by Mr. L. J. Newman, Entomologist of the Department of Agriculture. In the vicinity from which it was first reported in Australia it is believed to have been introduced amongst some soil which had been used as ship's ballast, and was taken for reclamation work along the foreshore. While the means by which the pest was introduced will never be definitely known, there is a certain amount of justification for the foregoing theory, particularly when it is realised that Bunbury had a large trade with South Africa in jarrah sleepers, and very little back loading, which necessitated boats returning in ballast. It is also significant that the pest is well known in the southern provinces of the Union under the name of Black Sand Mite.

The writer's attention was drawn to a pest by Mr. W. S. Kelly, of Giles Corner, and the similarity of this mite to the Western Australian pest caused him to have specimens forwarded to Victoria and Western Australia for identification.

Mr. L. J. Newman, in a letter to the writer, expressed the opinion that the specimens were identical with the western pest, and designated them as *Penthaleus destructor*, while Mr. C. French, jun., Entomologist of the Victorian Department of Agriculture, was of the opinion that the specimens were identical with the Pea Mite of that State, and designated them as *Notophalus bicolor*. But Newman further points out that the western species was at one period considered to belong to the genus *Notophalus*.

Further, Dr. Davidson, of Waite Agricultural Research Institute, in a letter to the writer, states that the specimens forwarded to him are *Penthaleus destructor*. From the above evidence it would appear certain that the Red-legged Earth Mite of Western Australia is already in South Australia and extends into Victoria.

### ITS SOUTH AUSTRALIAN DISTRIBUTION.

The pest has been observed as being widely distributed in this State, and its presence has been noted in the following districts:—Mount Bryan, Booborowie, Redhill, Owen, Windsor, Riverton, Tarlee, Eudunda, along the River Murray at Murray Bridge, and at Mount Gambier, which indicates the pest is well established within our borders.

### THE PEST.

The mite is eight legged, of a blackish-purple body color, with reddish legs, being about one twenty-fifth of an inch in length. It moves rapidly over the surface of the ground, or host plants, but when on the latter, if disturbed, it quickly drops to the ground and rapidly seeks cover. The anterior pair of legs appear to function as antennae, being frequently waved high in the air as the mite travels.

### ITS LIFE HISTORY.

It makes its appearance in early autumn, after the first rains, and continues its ravages until the advent of warm weather. Prior to the dying off of the adults at the approach of summer, the females lay eggs capable of withstanding arid conditions, thus being the means of carrying over from season to season.

With the return of more humid conditions the eggs hatch, when a six-legged larva emerges. In a few days, however, the larva undergoes several moults and emerges as an eight-legged mite

3. Adult male, magnified by 20.
4. Adult female, ventral view, showing eggs in body magnified by 20.

COMPARISON WITH THE LUCERNE FLEA (*Smynthurus viridis*).

Although outwardly the ravages of these two pests are similar, and their ultimate result the same, they in no way resemble each other as to color, shape, or manner of feeding. In regard to the feeding habits of the flea, Holdaway describes its mode of feeding "as a combination of gnawing and chiselling, consuming one epidermis and the underlying mesophyll tissue down to the other epidermis." While Newman describes that of the mite "rasping rather than for piercing; the surface of the leaf is broken, and the sap sucked up, the whole of the green parts removed."

Thus it will be seen that whereas the use of arsenical sprays may be helpful against the flea, they cannot be of use against the mite.

The season of activity is identical, and the two pests can be found working on the same plants at the same time.

#### COMPARED WITH THE RED SPIDER (*Bryobia pretiosa*).

It becomes evident upon comparison that the Red Spider is a web insect, whereas the mite is not. Further, the Red Spider does not readily drop to or travel over the surface of the soil in the rapid manner so characteristic of the mite. Finally the mite makes its appearance in the cooler, damper periods of the year, whereas the spider is prevalent only during the warmer months.

#### CONTROL.

Satisfactory means of control have yet to be evolved, but as a means of prevention the use of any well-known contact spray can give some protection to plants.

In gardens care should be exercised in obtaining seedlings from districts free from the pest, or the plants should be carefully dipped prior to planting in some recognised spraying solution. Carefully removing all rubbish and litter from the soil and deep digging also assist, while seedbeds may be protected by a trail of phenol, or borders upon which tanglefoot has been spread. The use of powdered naphthalene is in a slight way effective, but the greatest control in field conditions will be effected by fallowing.

#### HOST PLANTS.

The mite is a most cosmopolitan feeder, attacking all winter growing plants, but has a special liking for the more luscious types, such as Chick Weed (*Stellaria media*), Cape Weed (*Cryptostemma calendalaceum*), Peas, Beet, and Potatoes.

## LACK OF ARSENIC TO BLAME !

ON THE QUESTION OF INEFFICIENT SHEEP DIPS—

Many dips on the market contain a low percentage of arsenic, yet they are called ARSENICAL DIPS, but are inefficient.

## YOUNG'S SHEEP DIP

(POWDER)

complies with the requirements of the Stock and Brands Department for South Australia, and contains considerably more than the percentage of Arsenic stipulated under the Act, and will KILL TICK and LICE, and resist the Blowfly attack.

Try also YOUNG'S BRACKISH WATER SHEEP DIP. Mixes readily with Fresh or Brackish Water.

FROM ALL STORES.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

### CONFERENCE OF MURRAY LANDS BRANCHES.

The eleventh Annual Conference of Agricultural Bureaux situated in the Murray Mallee Lands Districts was held at Alawoona on Tuesday, September 30th. Messrs. H. S. Taylor (member of the Advisory Board of Agriculture), Professor A. J. Perkins (Director of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), R. C. Scott (Supervisor of Experimental Work), L. Smith (Manager Veitch Experimental Farm), R. L. Griffith (District Agricultural Instructor), P. H. Suter (Senior Dairy Instructor), C. McKenna, B.V.Sc., M.R.C.V.S. (Government Veterinary Officer), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau) represented the Department of Agriculture, and there was an excellent attendance of delegates from the following Branches:—Karoonda, Caliph, Paruna, Alawoona, Taplan, Bugk, Nunkeri, Yurgo, Wanbi, Loxton, Porrika, and Copeville.

#### THE OPENING ADDRESS.

Mr. W. Paul (Chairman of the Alawoona Branch of the Agricultural Bureau) presided over the Conference. Mr. H. S. Taylor (member of the Advisory Board of Agriculture), in opening the Conference, spoke of his first visit to Alawoona, nearly 20 years ago, on the occasion of a Parliamentary celebration of the completion of the Brown's Well line as far as Wanbi. A drive, which was largely a walk, over the interminable sandhills between Veitch and Alawoona, and the stunted nature of the mallee had not favorably impressed the party used to the much larger growth of the scrub further north; and he recalled the grave doubts expressed by that sturdy pioneer, the late Hon. John Lewis, as he surveyed the unbroken mallee at Wanbi, as to whether anyone could ever make a living in such country. The speaker, remembering his own father-in-law had been starved out of the Mindarie country—which he was the first man to take up, nearly half a century earlier—found himself sharing these doubts.

By their enterprise, hard work, and courage, backed by the splendid spirit of their wives and womenfolk, the mallee farmers had turned this land, for so long regarded as useless, into a valuable asset to the State. They had proved its possibilities and demonstrated that in average seasons good crops could be grown in it.

They had done more than add to the wealth of the State. There was a profound and pregnant truth in the old Greek fable of Antaeus. It was from the land that the nation drew not only its material wealth but those moral qualities of courage, steadfastness, self-reliance, and endurance, and, he would add, faith and unconquerable hope, on which a nation relied in times of stress and crisis, and which were the ultimate foundations of national greatness.

Napoleon and Foch after him had stressed the importance of the moral factor in contributing to victory, and it was on the moral qualities developed in the struggle with Nature's stern forces that Australia must rely to carry it through the critical times now confronting it.

The mallee farmers and their families had had ample occasion during three years of unparalleled drought to call up their reserves of courage, fortitude, and hope. They had borne themselves magnificently, and it looked, though the issue was still uncertain, as though they had won out triumphantly over the adverse forces of Nature—only to be faced by problems as difficult in the economic world that were not of Nature's making but were due to the mistakes and short-sightedness of man.

That they would emerge from the struggle, not without honorable scars, but victorious and with unconquered spirit, must be the fervent hope of every true Australian. Dark as was the price outlook at present, the Commonwealth Statistician, Mr. Wickens, had lately forecasted a realisation of 4s per bushel on the coming season's wheat, and he was delighted to learn that Professor Perkins, in large measure, shared in Mr. Wickens's optimism with respect to comparatively good prices in the near future. He trusted that the Conference deliberations would contribute to the solution of the difficult problems with which the mallee farmer was faced.

The following papers were read and discussed:—"Farm Book-keeping," Mr. W. H. Todd (Caliph); "Rural Economics," Mr. T. B. Flint (Alawoona); "Horse Management," Mr. W. G. Sutherland (Copeville).

During the session devoted to Free Parliament, Conference resolved, on the motion of Mr. T. Flint (Alawoona), seconded by Mr. Edwards (Bugle), "That the Department of Agriculture be requested to continue to carry on the work of investigating costs relating to the growing of wheat."

It was decided to hold the 1931 Conference at Alawoona.

Mr. Paull (Alawoona) moved—"That this Conference views with alarm the press reports that there was a possibility of the Veitch Experimental Farm being closed, and enters a strong protest against any such action if contemplated by the Government." The motion was seconded by Mr. W. Todd (Caliph) and carried.

On the motion of Mr. Paull (Alawoona), seconded by Mr. T. Flint, it was resolved—"That the Government be asked to secure two entires (Clydesdales), to be stationed at Veitch Experimental Farm, and travel the district."

It was decided—"That this Conference desires to bring to the notice of the authorities the desirability of establishing a branch of the State Bank at Alawoona at an early date in order to help the development of the district."

Mr. F. Richards (Caliph) moved, and Mr. G. Sutherland (Copeville) seconded—"That prior to the 1931 Conference each Branch represented appoint two of their members to act as delegates to vote on business matters that come before the Conference."

An interesting discussion took place on reducing the costs of production in the mallee, and, following a request from the Conference, Professor Perkins undertook to address the 1931 gathering on the subject of reducing costs of production and the best methods to adopt to increase production.

On the motion of Mr. G. Sutherland (Copeville), seconded by Mr. Collins (Copeville), it was resolved—"That the Advisory Board be requested to consider the advisability of dividing the present Murray Mallee Lands Conference district into two Conferences."

The Conference concluded with an address by Mr. H. B. Barlow (Chief Dairy Instructor) on "Dairying for Farmers in the Mallee Areas."

### DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD, & Co., LIMITED, reported on October 1st, 1930:—

**BUTTER.**—The production of butter in South Australia is now heavier than for many years past, due to the fact that nice growing weather has been experienced in most of the dairying districts, and supplies are still increasing each week. With the continuance of spring rains there is every probability of the season extending later than usual, which would mean that the production would maintain for some time yet. Meanwhile the surplus butter is being packed for London, and the standard is high. Rates have continued steady, but there is a weakening tendency in the London market which may be reflected in values a little later. Choicest creamery fresh butter in bulk, 1s. 4½d. Prints and delivery extra. Second and third grades, 1s. 2½d. (These prices are subject to the stabilization levies.) Best separators, 1s. 1½d. to 1s. 2½d. Well-conditioned store and collectors', 10½d. to 11½d. per lb.

**EGGS.**—Very heavy supplies are now being marketed from all country districts, and owing to the lower prices ruling for grain the production throughout the State is likely to be a very heavy one. Meanwhile heavy quantities are being graded and packed for London, and the surplus is being absorbed by pulpers and picklers for winter use. The market is steady. Ordinary country eggs, hen, 6½d. per dozen; duck, 7½d. per dozen.

**CHEESE.**—The South-Eastern factories are producing very heavy quantities, and the season looks as though it will be almost a record one. Rates eased during the month, but so far there has not been much accumulation of stocks in the city, and local and Western Australian buyers are purchasing steadily from week to week. New makes, large to loaf, 7½d. to 8d. per lb. semi-matured and matured, to 1s. per lb.

**ALMONDS.**—The demand for almonds continues strong, and as the supplies coming forward are only limited, ready sales can be made for all lots offering. Kernels also are selling freely at quotations. Brandis, 8d. to 8½d. per lb.; mixed softshells, 7d. to 7½d.; hardshells, 4d. to 4½d.; kernels, 1s. 7½d. per lb.

**HONEY.**—The demand for honey is dull. Odd parcels of prime clear extracted are clearing, but most sales are hand to mouth purchases from small buyers. The sales of lower grades, however, are very limited, and heavy stocks are being held. Prime clear extracted in liquid condition, 4½d. to 5d.; best quality candied lots, 4½d. to 4¾d.; second grade honey, 2½d. to 3d. per lb.

**BACON.**—The demand for bacon has kept up well all things being considered, and as curers are able to obtain full supplies of live hogs ample quantities of all cuts of bacon and hams are being marketed from week to week. Values have been without much fluctuation. Best local sides, 11½d. to 1s.; best local factory cured middles, 11½d. to 1s.; large, 10d.; local rolls, 11½d. to 1s.; Geo. Farmer's "Sugar Cane" brand lard in packets, 11d. per lb. in bulk, 10d. per lb.; local lard, 10½d. per lb. in prints.

**LIVE POULTRY.**—The sales for live poultry have well maintained throughout the month. Demand was stimulated by the Agricultural Show held a few weeks back, but supplies since have been somewhat lower than usual, and buyers have been unable to obtain all their requirements. It is anticipated therefore that the strong demand will continue, and there is ample demand for all lots consigned. We advise consigning. Crates loaned on application. Prime roosters, 4s. 6d. to 5s. 6d.; nice-conditioned cockerels, 3s. 6d. to 4s. 3d.; fair-conditioned cockerels, 2s. 9d. to 3s. 3d.; chickens, lower; heavyweight hens, 3s. 6d. to 4s. 6d.; medium hens, 2s. 9d. to 3s. 4d.; light hens, 2s. 3d. to 2s. 6d.; couple of pens of weedy sorts, lower; geese, 4s. to 6s.; prime young Muscovy drakes, 4s. 6d. to 5s. 9d.; ducks, good conditioned, 3s. 6d. to 4s. 3d.; ducks, fair condition, 2s. 4d. to 3s.; ducklings, lower; turkeys, good to prime condition, 8d. to 11d. per lb. live weight; turkeys, fair condition, 6½d. to 7½d. per lb. live weight; turkeys, fattening sorts lower; pigeons, 7d. each.

**POTATOES.**—Best South-Eastern and Victorian, 6s. 6d. to 7s. 6d. per cwt.

**ONIONS.**—Best onions, 6s. per cwt.

## VEGETABLES

*good health demands them!*

Only by eating vegetables frequently can we maintain our blood in good condition, and therefore, our health. This fact is not sufficiently realised.

Made in handy tablet form, Swallow & Ariell's Compressed Vegetables are equal in every way to fresh, as only water is removed, and their true flavour is retained. Easily prepared and economical—one pound of the compressed article goes as far as ten of the fresh—they take up so little space that they're easily stored.

With this product of Swallow & Ariell at hand you need never be short of health-giving vegetables. Buy a few packets now!

# SWALLOW & ARIELL'S COMPRESSED VEGETABLES

No report received during the month of September.

‡ Held over.

R In recess.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

#### SOUTH-EAST DISTRICT.

##### COONAWARRA.

Mr. Alder presided over an attendance of 17 members at the meeting held on July 10th, when Mr. F. Darwent presented an excellent paper, "Cultivation." (Secretary, Mr. H. A. Lynden.)

KALANGADOO WOMEN'S (Average annual rainfall, 32.30in.).

Meeting held July 12th. Present: 16 members. Mrs. Dowdell gave a demonstration of rug making. (Secretary, Miss A. Kennedy.)

KYBYBOLITE (Average annual rainfall, 22in.).

Meeting held June 10th. Present: 20 members. Mr. Schinkel read a paper, "Manuring Pastures." Mr. D. Quinn also read a paper, "Orchard Pests." An excellent discussion followed the reading of each paper.

Twenty members and three visitors attended the meeting held on July 5th, when Mr. W. H. Downes (District Dairy Instructor) read a paper, "Pig Raising." (Secretary, Mr. F. H. Martin.)

MILLICENT (Average annual rainfall, 29.70in.).

June 27th.—Present: 10 members.

POULTRY AS A SIDE LINE.—Mr. K. Skeer read the following paper:—"Better chicks were raised from hens three years or older, but when the hens passed the third year they were not so profitable from an egg-producing point of view. Branding the eggs was a good thing, as it placed the responsibility for bad eggs on the right persons. Never set eggs of less than 2oz. in weight nor very large ones. Iodate of potash fed to breeding hens was said to ensure more reliable hatching. Eggs were preferred when no roosters were kept, and ensured a better price when they could be relied on as infertile. It was better to separate the sexes as soon as distinguishable, but there was not a very great demand for this class of poultry locally, and the city market was too far away. Barley was preferred by some as the best egg-producer in this cold climate. Where fowls were running out, two feeds per day were sufficient. As much grain as they would eat in 20 minutes was a simple means of finding out the quantity to feed to a flock. If it was not possible to link up with the Red Comb Association, if a number of persons went in for the business on approved lines, they could form an association of their own. Fifty fowls of the right ages and breeding would give better results than 100 nondescripts of uncertain age and type. (Secretary, Mr. E. Mitchell.)

MILLICENT WOMEN'S (Average annual rainfall, 29.70in.).

The inaugural meeting of the above Branch was held on June 20th and was attended by 13 members. Officers were elected.

Fifteen members were present at the meeting held on July 18th. Members discussed the subject, "Different Ways of Using in the Kitchen Surplus Piemelons, Pumpkins, and Marrows." Mrs. L. Oberlander tabled samples of pumpkin scones. (Secretary, Mrs. W. Varcoe.)

##### RENDELSHAM.

Meeting held July 19th. Present: 13 members and six visitors. During the afternoon Mr. H. Orchard (District Horticultural Instructor) gave a pruning demonstration in Mr. F. White's orchard, and in the evening read a paper, "Principles of Pruning." Trophies were presented to the winners of the Potato Competition—Messrs. S. Smith first, and W. Andrews second. (Secretary, Mr. F. R. White.)

**TANTANOOLA.**

Meeting held July 5th. Present: eight members and visitors. The annual report was presented and officers elected for the ensuing year. (Secretary, Mr. H. M. Kennedy.)

**TATIARA (Average annual rainfall, 19.39in.).**

The annual meeting of the Branch was held on July 9th, there being present 20 members and two visitors. The annual report was read and addresses were delivered by Messrs. E. S. Alcock and — Lyons. (Secretary, Mr. L. H. Butler, Bordertown.)

**UPPER-NORTH DISTRICT.****(PETERBOROUGH AND NORTHWARD.)****APPILLA (Average annual rainfall, 15.01in.).**

Mr. G. Wurst presided over an attendance of 12 members at the annual meeting which was held on July 4th. Messrs. G. Wurst and C. Borgas were presented with Life Membership Certificates of the Agricultural Bureau and officers were elected for the ensuing year. (Secretary, Mr. E. H. Wurst.)

**BLACK ROCK (Average annual rainfall, 12.57in.).**

Meeting held July 1st. Present: Nine members. The annual report was read, and officers elected. Mr. E. L. Orchard (District Agricultural Instructor) addressed the meeting. (Secretary, Mr. R. Kitto.)

**EURELIA (Average annual rainfall, 13.14in.).**

On the occasion of the Annual Meeting, which was held on July 9th and attended by 12 members and three visitors, officers were elected for the forthcoming year. Mr. E. L. Orchard (District Agricultural Instructor) delivered an address, "Maintenance of Soil Fertility." (Secretary, Mr. E. Wall.)

**EURELIA WOMEN'S (Average annual rainfall, 13.14in.).**

At the meeting held on July 9th the annual report was presented by the Secretary, Mrs. I. M. Wall. Officers were elected for the ensuing year. An address was delivered by Miss Campbell, of the Education Department. Twenty-four members and visitors attended.

**MORCHARD (Average annual rainfall, 13.50in.).**

July 4th.—Present: 11 members.

Mr. C. Halliday read a paper, "Grading Wheat."

**MANAGEMENT OF THE FARM FLOCK.**—The following paper was read by Mr. N. Lillecræpe:—"In dealing with this subject it is not my intention to lay down any hard and fast rules for managing a farm flock, as we all recognise that circumstances alter cases and conditions in Northern areas differ from those in the South. Most of the information and hints given in this paper have been gained from personal experience, and may be of use to others. Sheep are a very necessary adjunct to a farm, even though wool prices have fallen considerably they are still a very profitable sideline, and can also be utilised as labor savers in cleaning up fallows after shearing. The Merino is generally recognised as the most profitable sheep for a dry climate. Avoid old sheep if possible, particularly old wethers; they will not fatten, will not breed a lamb, and their wool is generally light and unprofitable. If you keep a permanent flock, cull the aged sheep every year. Also cull coarse, hairy woolled sheep. If there are not too many it is a good plan to kill them off for rations. Try and make the flock as even as possible, both in type and in wool. This will obviate the necessity for much classing at shearing time. Do not keep sheep in one paddock too long. Change the pasture often and they will do better, and you will be able to carry more sheep. They should always have access to water if possible. For raising fat lambs I recommend large-framed Merino ewes crossed with a Dorset ram. Procure two or four tooth rams if possible; the older rams become fat and lazy. The Dorset cross develops quickly, and at four months old should be ready for market. This lamb seems to stand the long rail journey better, does not waste or lose bloom like the pure Merino, and on account of weight and size realises a much better price. Get the lamb matured by August, if possible, as the price generally declines from then on as the number on the market increases. If you are unable to fatten crossbred lambs do not hold them if you can possibly sell, as they are an unprofitable line to keep for wool, and are usually bad

fencers. When shearing have everything in readiness before you start. Have the yards convenient, the shed, tables, press, bins, &c., clear, and see that there is plenty of shed room for penning sheep over night. Do not crowd them; the hot, steamy air of a close shed tends to raise the yolk and discolor the wool, especially if the wool is inclined to be yellow. I would not advise making more than two classes of small clip, but if the backs are inclined to be dirty, take them out and bale them separately. The dust from a few backs will permeate the whole bale when pressed, and reduce the value of the clip. Keep the best fleeces as uniform as possible and free from breaks. Brand these AA. The short, yellow, and heavy-conditioned fleece should be baled separately and branded A. Locks and stains should be dried before baling. Number and brand the bales neatly, and put the clip up as attractively as possible. Any member who reads his *Journal* should know how to put up his clip for market. Do not neglect to brand the sheep after shearing, unbranded sheep are difficult to trace. The owner of a registered brand is allowed to use any numeral from 2 to 9 as a flock mark, may earmark his sheep with any earmark he thinks proper, and may attach tags to the back of the ears of sheep. An earmark is handy to distinguish the sex of lambs when drafting or marking any particular line you wish to keep. When marking lambs in cold weather an antiseptic is not necessary, but in warm weather when flies are prevalent it is advisable to use Cooper's Milk Oil Fluid or thin medicated oil to protect the wound. Do not use Stockholm tar or any preparation that is liable to close up the wound too soon, this will cause blood poisoning. Sheep as a rule are fairly free from disease in a dry climate, except for "pink-eye." This generally causes total blindness for a time of one, and sometimes both, eyes. It is best to isolate the blind one if possible to prevent contagion. Treat the affected eye with boracic acid. The eye will usually respond to treatment if taken in time." (Secretary, Mr. A. McCallum.)

WARCOWIE (Average annual rainfall, 12.16in.).

The Annual Meeting of the Branch was held on July 10th, and was attended by 10 members and visitors to the number of about 100. After formal business had been transacted Mr. E. L. Orchard (District Agricultural Instructor) delivered an address in which he gave an interesting description of the history of flour and bread making. The meeting then took the form of a concert and dance. Supper was provided by the ladies. (Secretary, Mr. A. F. Crossman.)

WILLOWIE (Average annual rainfall, 12.27in.).

The meeting of June 17th was held at the residence of Mr. A. Bartlett. A demonstration of pig killing and sheep dressing was given by Mr. E. Davis, who was assisted by Messrs. A. Crisp and S. Brooks. Afternoon tea was provided by the ladies. (Secretary, Mr. H. Crisp, Booleroo Whim.)

## MIDDLE-NORTH DISTRICT.

### (PETERBOROUGH TO FARRELL'S FLAT.)

BELALIE NORTH (Average annual rainfall, 17.95in.).

July 7th.—Present: Nine members.

SHARE FARMING.—Mr. F. Carmichael read the following paper:—"Share farming has its advantages and disadvantages. There are different methods of share farming, namely, the half system and the third system. The landholder finds all the seed and super where the share farmer does not live on the property, but if the share farmer resides on the property it is customary to work the land on the half system. The share farmer finds half seed and super. With the half system an advantage is gained by a young man wanting to start out on his own. It is a good way of getting a start, as the young man will get a plant together, and get a footing before he buys a farm on his own account. Another advantage is that the landholder has not the responsibility of the upkeep of the plant, which is a heavy item at times. He would be able to run more sheep, and keep the fences in repair when not attending to the sheep. Another advantage is that the farmer with sons who has not sufficient land to keep them all at work, and is able to get share farming for his boys, can give the sons a start by that method, and an interest in the work on the farm. One of the disadvantages of share farming is where a farmer has sons going to school and lets his land on shares; this has a tendency to make the boys lose interest in the farm. Again, sometimes the share farmer does not work the land to the best advantage. For instance, they are not usually very fond of picking stones, and leave the stones from time to time, which makes the land very rough on implements. Share farming is a very good practice, for it relieves the landowner of worry of employing men and the upkeep of machinery, and it is a cheap and easy way for a young man to get plant and capital together for a farm of his own. (Secretary, Mr. E. Carmichael, Jamestown.)

**BEETALOO VALLEY** (Average annual rainfall, 23.50in.).

There was an attendance of ten members at the meeting held on June 9th. Discussion was devoted to making arrangements for the annual social. (Secretary, J. Halse.)

**BLYTH** (Average annual rainfall, 16.94in.).

Meeting held June 27th. Present: Mr. A. McEwin (Chair) and 18 members. Mr. E. Lanyon read a paper, "Will Power Farming Survive Low Yields and Reduced Prices for Wheat?" (Secretary, Mr. L. Mugge.)

**EVERARD EAST.**

Fourteen members attended the meeting held on July 9th. Mr. W. Johnston (District Agricultural Instructor) delivered an address, "Fertilisers." The meeting then took the form of a social evening. (Secretary, Mr. F. T. Hughes, Blyth.)

**GLADSTONE** (Average annual rainfall, 16.44in.).

Twenty-four members attended the annual meeting, which was held on July 11th. Officers were elected for the forthcoming year. (Secretary, Mr. F. Chick.)

**KOOLUNGA** (Average annual rainfall, 15.61in.).

Meeting held July 8th. Present: Mr. H. Spencer (Chair) and nine members. Mr. F. Pedler read an instructive paper, "Fallowing."

**NARRIDY** (Average annual rainfall, 15.99in.).

Meeting held June 21st. Present: 17 members. Mr. E. Richards contributed an instructive paper, "The Use of Increased Quantities of Super." Officers were elected.

**BACON CURING.**—The following paper was read by Mr. E. Klinger at the meeting on July 5th:—"The pig to be killed should be fasted at least for 24 hours to clean the system, but should have all the drinking water it requires. Care must be taken not to get the animal heated or excited, otherwise the flesh will be more difficult to cure and the bacon less palatable. I recommend shooting the pig. A .22 calibre rifle will answer the purpose, after which turn the pig on its back and stick it just in front of the breast-bone, driving the knife straight in and a little downward. When the knife is in, press the handle down a little to raise the edge of the blade, as to cut both jugular veins. Then turn the pig on its side to facilitate bleeding. The carcass should be ready for scalding a few minutes after killing. For scalding, I recommend a large vessel to dip and immerse the carcass. The water for scalding may be made up as follows:—For coarse-skinned or hairy pigs, three parts boiling water to one part of cold, and for young and tender-skinned pigs two parts boiling water to one of cold. For scraping, a saucepan lid or a blunt knife will answer the purpose. When the carcass is scraped clean, hang it up at a convenient height for disembowelling. To do this, make an incision from between the hind legs and continue right down to the lower jaw or chin, care being taken not to cut too deep, and thus puncture the intestines. To avoid this, place one hand in front of the intestines and guide the knife between the fingers. After cutting right down, start at the top, between the hind legs, and remove all the intestines and stomach, but before doing this, securely tie the end bowel. Next cut the diaphragm or lining between the stomach and lungs and take out the heart, lungs, windpipe, and tongue. This should leave the carcass clean and unsoiled. The head may be removed or left on as desired. The carcass should be left hanging in an airy place until next morning so that the flesh will set. In the morning, before sunrise if possible, cut the carcass straight down the backbone or cut down on both sides of the backbone. The latter method makes cutting up easier. When cutting up, first cut out the hams, then the shoulders. The sides or flitches are then trimmed by cutting off any surplus fat. The ribs can also be taken off, keeping as close to the bones as possible in order not to remove too much of the lean flesh. After trimming the hams and flitches they are ready for curing. This may be done in two ways: either by dry salting or pickling in brine. For dry salting, a little saltpetre should be rubbed into any veins and all bones. Then thoroughly rub salt into every part. This must be done every day for about a fortnight, more or less, according to the weight of the pig, always turning the meat and letting any moisture drain off. For brine pickling, the brine must be made up by putting enough salt into the water to float a fresh egg. Then boil and skim off any scum that may rise. When cold a little saltpetre and a few bay leaves are added, and a little sugar may also be added and the meat placed in a convenient vessel and the liquid poured over it. In the latter way the meat to be turned and left in the brine the same as in the first way. Always see that the meat is well drained before pickling, and keep it in a cool place while being cured. Hams will take longer to cure than bacon. After the meat is pickled, hang it up and thoroughly drain it. Then it is ready for smoking. To do this, hang it in a place where the smoke

can be confined. Place some coals on the floor and cover with sawdust or fine chips that will smoulder and send forth a good volume of smoke. If the sawdust or chips are too dry, dampen a little, otherwise it will burst into flame and cause the fat to melt and spoil the flavor. When the meat is a rich brown it will be smoked enough. After smoking place the cured meat in calico bags and hang in a cool, dark place." (Secretary, Mr. H. B. Cox.)

**NORTH BOOBOROWIE** (Average annual rainfall, 16.35in.).

Eight members and eight visitors attended the meeting held on June 9th, when Mr. E. L. Orchard (District Agricultural Instructor) delivered an address, "How to Increase Farm Production." (Secretary, Mr. H. Mudge, Willalo.)

**REDHILL** (Average annual rainfall, 17.02in.).

Meeting held July 8th. Present: Six members. Mr. J. Clothier read a selected paper, "Barley," and a keen discussion followed. The annual report and balance-sheet were presented, and officers elected. (Secretary, Mr. S. A. Pengilly.)

**YANDIAH.**

Meeting held June 20th. Present: 18 members and visitors. Mr. J. B. Harris (District Horticultural Instructor) gave an address, "Pruning and Planting Fruit Trees." (Secretary, Mr. F. Jettner.)

## METTER'S "NUOIL" DOUBLE GEARED SELF-OILING WINDMILLS.

IN SIZES FROM 6ft. TO 14ft. WHEEL.

The strongest, best lubricated, best designed, and best governed.

Pump more water on a lighter breeze.

No spring on automatic oiling system to break, and no sheet-metal oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923, 1924, 1925, 1926, and 1930 (no entry 1928-29).

Also Gold Medal at the All-Australian Exhibition, 1930.

A reliable and useful investment, and the popular choice of experienced pastoralists, farmers, and others.

### METTER'S 5ft. "MINOR" WINDMILLS.

Most efficient for pumping water from shallow depths.

MILL ONLY, £9 15/0; on 15ft. G.I. TOWER, £15 15/0; on 20ft. TOWER, £17 17/6.

### METTER'S FUEL STOVES AND WASHING COPPERS.

Use less fuel and retain heat longer.

WHOLLY MANUFACTURED IN SOUTH  
AUSTRALIA BY

Mr. J. Heinrich presided at the annual meeting, which was held on July 8th, there being present 10 members and visitors. Mr. W. Johnston (District Agricultural Instructor) gave an address, "Farming Fallacies." (Secretary, Mr. K. H. Dunn.)

**BRINKWORTH (Average annual rainfall, 16.0lin.).**

July 7th.—Present: 20 members.

**CONSERVATION OF FODDER.**—The following paper was read by Mr. C. Ottens:—"This subject generally receives careful consideration, and is never overlooked by careful farmers whose stock must have sustenance all the year round. During the past few years we have experienced adverse climatic conditions, when for many months there has been little or no feed from natural pastures. It is in these periods that the farmer realises the value of conserved fodder. The man farming around Brinkworth, and especially on the Condowie Plains, where little or no summer fodder grows, should pay the most attention to the quality and quantity of hay he proposes cutting. A man working a 700-acre farm with 12 horses should cut approximately 50 tons of hay per annum—harvest permitting—and in prosperous seasons stack aside a considerable surplus, to enable him to sustain his stock through lean times. A profitable reserve would be 100 tons of hay built in two stacks of 50 tons. Select good hay, wheaten hay in preference to oaten hay, on account of the latter being liable to be affected by mice. Cut the hay before the crop is too far advanced. Much value is lost by cutting too late, and avoid cutting rusty hay on account of the bad effect it has on horses, while nothing will be gained by cutting hay from wheat wherein smut is prevalent. Immediately the hay has been stacked it should be given a thick covering of straw to protect it against rain and sun. The most suitable corn fodder for horses, cows, and sheep is oats, barley for pigs, wheat for fowls, and peas are also a valuable foodstuff where it is possible to grow them. Every farmer should have at least two small paddocks of about 20 acres for the purpose of sowing oats and barley every alternate year; this would supply the average farmer with an annual supply of corn, and in most seasons could be fed off two or three times in its growing stage and still yield a profitable return. Oats and barley should be crushed before feeding, on account of a lot of the grains passing through the animals undigested. Should the corn crib become overstocked, there is a saying, "Turn barley into pork," and the same applies to oats; the grain can be boiled, and a farmer could fatten two or three times as many pigs without any extra milk supply. A thrifty farmer will also pay attention to the gathering of dry fodder, such as straw and cocky chaff. This backs up his hay supply, especially in dry seasons, and takes a very prominent part on the feeding chart at the present time, and has, no doubt, proved itself a boon to farmers in drought-stricken areas. A suitable sized straw stack, stacked in January and enclosed until about June, will provide stock with shelter, feed, and an occasional grooming during the winter months, and is well worth the energy spent erecting it. In wet seasons, when the straw is a fair length, it is advisable to cut sheaf straw. Straw mowed with a grass cutter and well stacked will keep 10 to 12 years, and be of better feeding value than when it was stacked; a stack of reserve straw in an odd corner will not be out of place on any farm. During the last two years there has been a great demand for cocky chaff as a fodder (when only five years ago its main use was for packing eggs). It is a good substitute for hay chaff, provided it is mixed with corn and molasses. Cocky chaff, if fed dry, is liable to cause stoppage in horses, a difficulty that has presented itself quite frequently of late, and in many cases has been the cause of a premature death to a valuable horse. Its chief value is as a standby in dry seasons, or for mixing with good, rich hay chaff. With the growing popularity of the reaper thresher, cocky chaff is losing a lot of its feeding value on account of the amount of straw these machines have in their chaff, while the stripper and harvester only leave chaff and flags of the straw, which, if carted before the first rain and conserved in an old shed in good repair, and shielded from the rain, will keep fresh and sweet for a much longer period than if it is stacked out in the open with only a straw covering to protect it. In this case, to obtain best results, it should be fed within nine months of when it was placed there. **Pasture Fodder.**—The only items worth noting are—to obtain best results, topdress pasture by broadcasting with 90lbs. super per acre, and avoid overstocking. On the average 600 to 700 acre farm, poor seasons or good seasons 150 acres of pasture would be the most payable position. In very wet periods, when the land is thoroughly sodden, it is advisable to keep animals, especially horses, off the pasture on account of the damage caused when they are tramping around.

A small area of lucerne is also a very valuable asset for summer green fodder, especially for milch cows. The only drawback it has in this district is that it cannot be grown successfully without irrigation, nevertheless, a patch a chain square could be attended to quite conveniently, and will provide two or three cuttings during a season. It is rather a striking fact that farmers in this district do not seem to take advantage of ensilage. Most farmers say it is too much trouble and expense, but it is not when it comes to be proved how much feeding value there is gained by it. Ensilage can be made from a crop soon after it is out in ear, or from self-sown feed, such as wild oats, having enough growth to be able to cut with a binder. It should be cut at the flowering stage, and chaffed and stored the same day, a job that will occupy three men. The first and most important point is erecting a silo. The underground is preferred, and should be erected near the chaffcutter. All that is required after the silage has been stored is a covering of boards, over which should be placed a layer of earth to prevent it being spoilt by atmospheric conditions. If preserved properly it will keep two or three years, and have a considerable advantage over self-sown hay. The chief feature of ensilage is as a fodder for dairy cows. It can also be fed to horses, and is invaluable to mares with foals at foot. Ewes with lambs will also take to it after a little coaxing. Ensilage proves its greatest value to the small farmer who only keeps a few cows as a sideline in the autumn and early winter before there is any greenfeed, but the farmer who does extensive dairying will find it a valuable foodstuff during the summer months." (Secretary, Mr. H. E. Ottens.)

#### BUCHANAN.

Meeting held July 4th. Present: 11 members. The meeting was devoted to making arrangements for the Annual Social. A report of the Wasley Conference was presented by the Secretary, Mr. L. V. Bell, Marrabel.

CLARE (Average annual rainfall, 24.67in.).

July 1st.—Present: 23 members.

**DAIRYING AND PIGS.**—Mr. R. Baker, R.D.A. (Lecturer in Dairying, Roseworthy Agricultural College), delivered an address, "Dairying in New South Wales." Replying to questions, Mr. Baker explained that to overcome the possibility of milk fever when the cows were fat, it was usual to decrease the feeding just before calving time and also to give a drench consisting of 1lb. Epsom salts, 1oz. ginger, 1lb. treacle. The lecturer, in answering a question *re* the best type of bacon pig, outlined the points essential for a good baconer, namely, long middle, deep ham, light shoulder and back, and not a heavy jowl. This type could be obtained fairly closely by crossing the Tamworth or Large York with the Berkshire. The Tamworth was more favored than the Large York, probably because the Large York was not so well-known, but that pig had made the bacon trade of Denmark. It was also recommended by some to make a second cross of either Berkshire, Tamworth, or Large White, back on the first cross. With regard to licks, it was mentioned that a large number of licks sold by numerous business houses contained a high percentage of common salt. It was explained that the main deficiency, particularly with cows was that of phosphate, not common salt. The following useful mixture was recommended for cows at the rate of 3ozs. or 4ozs. per day in their feed:—Bonemeal, 45lbs.; coarse salt, 40lbs.; Epsom salts, 5lbs.; iron sulphate, 5lbs. In connection with pigs, it was mentioned that the addition of bonemeal reduced the actual feeding by 20 per cent. to 25 per cent. The following mixture was recommended as being satisfactory for pigs:—Wood, ashes, or charcoal, 15lbs.; common salt, 20lbs.; bone-

meal, 15lbs.; superphosphate, 15lbs.; iron sulphate, 4lbs.; Epsom salts, 4lbs.; baking soda, 6lbs.; sulphur, 6lbs. Potassium iodide could be added at the rate of 2ozs., but it was found not to be essential in the settled areas of South Australia. In the feeding of pigs with buck currants and raisins from the packing sheds, it was found that they acted as too much of a laxative. They could be used as 20 per cent. of the ration in conjunction with grain. Apples and pears had to be fed in great bulk to be of use to the pig. It took approximately 50lbs. of pears or apples to produce 1lb. of pork. It was also mentioned that it was more profitable to feed barley crushed and soaked for 12 hours only than whole and soaked. Skim milk and barley together were recommended as a good ration for pigs. (Secretary, Mr. A. Ninnes.)

#### LYNDOCH (Average annual rainfall, 23.70in.).

The annual meeting was held on July 10th and was attended by Mr. A. Springbett (Chair) and 18 members. The Secretary gave a resume of work performed by the Branch during the past year and officers were elected. (Secretary, Mr. J. S. Hammatt, Williamstown.)

#### MODBURY.

July 9th.—Present: 20 members and seven visitors.

**TOP DRESSING.**—Mr. W. Dalby read the following paper:—"In the early days of settlement in Australia, land not covered with forest or scrub was generally first-class grazing or pasture land. No wool was grown, no milk taken off, no mutton or beef, no horses, no grain, no wine or fruit, consequently all that grew was practically returned to the soil. Then came the white man requiring the production of fine white bread, wool for cloth, mutton and beef to eat, and leather to cover his feet, fruit and wine to tickle his palate, exports to cover imports. Consequently in a comparatively few years, land which once had been fertile ceased to produce equal to that of a decade earlier. No amount of resting or grazing of stock brought it back to its previous productiveness. In my boyhood days, resting land consisted of running as many sheep or cows thereon as it would keep for a year or two, and then another crop was sown with but scant success. Fallowing proved a great help; so great an influence has fallow on Australian productiveness that crops are seldom sown on any other than fallowed land to-day. Notwithstanding the cost of preparing land for cereal crops and the amount of labor expended, the crop would be poor, but for further expenditure in phosphate as fertiliser. Crops of 20bush. are now more or less common, and this represents the amount of phosphoric acid contained in 1cwt. of standard super. Thus the land has been improved slightly by any residue of phosphoric acid remaining after the crop has been removed, with corresponding improvement in grazing capabilities. This improvement led to experiment with super on purely grazing or pasture land with results quite as remarkable as its application to cereal crops. Without the aid of resowing, many of the best fodder plants, grasses, or clovers, thought to have been completely eaten out, reappeared and commenced to establish themselves and to add to the carrying capacity, and double that of virgin land. I have so improved the carrying capacity of grazing land by the application of 1cwt. of 45 super and 3lbs. of Subterranean clover as to keep healthy sheep where one poor delicate animal existed before, and this in a space of four years. And not only were the sheep healthy and strong, keeping in excellent condition, but the production of lambs increased 20 per cent., while deaths decreased from 10 per cent. to practically nil, or  $\frac{1}{2}$  per cent. in the last year for grown sheep, and other than the depredation of foxes, practically nil for lambs. For cattle, previous to top dressing, I used for cow and horse feed approximately 35 tons of hay annually at an average cost £2 10s. per ton. After the sowing of the Subterranean clover and 1cwt. of 45 super about seven tons of hay sufficed to feed both horses and cows. This left me with roughly 25 tons to 30 tons of hay to sell at £2 10s. per ton, or sufficient to pay for cost of super for top dressing purposes on the portion of land used for grazing only. Having by the aid of phosphate increased the grazing capacity of the land, care must be exercised that it does not lack other elements necessary, for in addition to super, three to five times the quantity of nitrates, nitrogen, and potash are absorbed, as well as that much iron and lime, &c. The application of iron in some lands is almost as necessary as phosphates and in others the application of lime. Should you at any time be in doubt and in need of advice, the Department of Agriculture is maintained to assist and will be glad to render advice or assistance. The general rise in land values compels greater production; less cost or higher prices and the financial cost and high taxation of land to-day compel something in the way of increased production."

**NANTAWARRA** (Average annual rainfall, 15.90in.).

Meeting held July 10th. Present: Mr. E. Hamdorf and nine members. An article, "The Principles of Vocational Guidance," was read by Mr. N. Robinson. (Secretary, Mr. N. T. B. Robinson.)

**PENWORTHAM.**

Meeting held July 10th. Present: 23 members and four visitors. Mr. A. R. Ninnes, of the Clare High School, gave an instructive address, "The Chemistry of Mixing Sprays," demonstrating with test tubes and glass containers the correct methods to adopt when preparing sprays. (Secretary, Mr. A. R. Jenner.)

**RIVERTON** (Average annual rainfall, 20.86in.).

The annual meeting was held on July 26th and was attended by Mr. D. Hannaford (Chair), 25 members, and 80 visitors. Life membership certificates of the Agricultural Bureau were presented to Messrs. J. Kelly, R. James, and T. Longbottom by the Hon. W. Hannaford. Prizes won in the 1929-30 Crop Competitions were also presented by Mr. Hannaford. Musical and vocal items were contributed. (Secretary, Mr. O. Longbottom.)

**SADDLEWORTH WOMEN'S** (Average annual rainfall, 19.65in.).

July 1st.—Present: 13 members.

**PUBLIC HEALTH.**—The meeting was held at the residence of Mrs. J. Frost. Mrs. Blundell read the following paper:—"During the past few years there has been a marked awakening throughout the world in matters of public health and the responsibility of Governments in this direction. The League of Nations has done a great deal to bring this about by internal exchange of ideas. The sphere of public health administration includes the effective carrying out of practices conducive to the health of the people, including measures of prevention which are the most important of all; also treatment of sickness and disease; the provision of hospital accommodation; the care and treatment of the blind, deaf, and dumb, and mental defectives; some measure of supervision and control in regard to town planning and housing; the encouragement of research work; the collection, preparation, and publication of statistics; and the training of persons for health services. In order to make State control effective, it is essential that there

should be a Central Health Department, supported by the organised co-operation of the medical profession. The central department has primary responsibility for the administration of the Health Acts. It is also important that there should be close co-operation between the Health Department and other Government services in any way connected with health matters. Until recently, health legislation has dealt largely with the environments in which people live and the food which they eat. There is still room for much improvement on these lines. With regard to food, the exposure of meat to the public gaze and to the dust and pollution of a city atmosphere should be prohibited. Meat should be kept in the background and in fly-proof cases. Bread is frequently seen in vans, by no means dust-proof, handled by hands not always clean, and stowed away carelessly. Is it any wonder that germs of disease are conveyed to the people who eat it? It is interesting to note that the Housewives' Association is taking up these matters and insisting to some extent on the laws of public health being carried out. If every woman felt it her duty to destroy immediately all vegetable and other refuse from the house, we should find that the hot weather fly pest would be greatly diminished. It is all very well to shut flies out of the houses, but it is the extermination of this pest that we should have in view. This leads us to consider the environments in which people live. It is only natural that city dwellers should be more effectively protected by health laws than are the people who live in the country. In rural districts there is a crying need for reform in sanitary conveniences. The most primitive conditions are in vogue in most farm houses. A septic tank can be installed for about £30. With an average rainfall of 10in. and a catchment of 150 square feet sufficient water could be supplied to work it, yet farmers think nothing of spending many hundreds of pounds on motor cars, wireless sets, and other luxuries. It is simply that we have become accustomed to these insanitary and inconvenient conditions and we do not think about them. Surely, it is our duty as women to agitate for reform. There is also scope for extension and improvement in the important field of maternal and child welfare. Adequate provision should be made by the public health authorities for all maternity cases in properly equipped and efficiently staffed hospitals. These hospitals should be subsidised by the Government. There is still much preventable maternal mortality in this country. This again is a matter which women should take into their own hands. The care of the health and well-being of its children is the natural duty of any country. There is no more valuable public health work than the periodic medical examination of school children. This is a work that should be carried out without a thought of the cost. Its return to the community by the discovery and arrest of early cases of tuberculosis will alone repay whatever money may be expended for this purpose. The teaching of hygiene or the care of the body in schools is most important. We know that the fight against tuberculosis infection is coming sooner or later in the life of the child, and that he or she must depend on general resistance to a great extent to prevent establishment of this disease. The school child should therefore be taught as early as possible the value of hygiene, proper feeding, proper exercise, and the value of fresh air and cleanliness. The public health laws in New Zealand give the necessary authority for medical examination of children attending all primary schools. The school medical service aims at securing for each child three complete physical examinations during his school life. Special examinations are carried out where parents, teachers, or the school medical officers consider them necessary. Children found to be suffering from defects are kept under observation until the necessary treatment is obtained. It is recognised that medical treatment must be available for every child in need of it, and that adequate provision must be made for the ill-nourished and neglected. Mentally backward and feeble-minded children are given special consideration. In our cities much valuable service is rendered by the Child Welfare Centres, it is a pity that this good work cannot be extended into country districts. There is still a gap to be filled in the supervision of a child's health between infancy and school age. However watchful the parents may be, it sometimes takes a trained eye to detect the beginnings of disorder or disease. The public health authorities do much valuable service in checking epidemics of disease. All infectious cases must be notified at once, and it is the business of the health officers to see that all necessary precautions are taken with regard to disinfection of rooms, clothing, &c. I have now touched briefly on the fringe of this wide subject, and what I want to bring before you is the urgent need for reform in matters of public health in South Australia. Our Government is too busy settling its financial worries to trouble very much about these matters. If only more women would interest themselves in better housing conditions, the Pure Foods Act, and problems of maternal and child welfare, much of the present misery and unemployment might be avoided." (Secretary, Miss D. Partridge.)

TRURO (Average annual rainfall, 20.21in.).

Mr. W. Johnston (District Agricultural Instructor) delivered an address, "Crop Rotations," at the meeting held on July 14th, which was attended by 17 members and visitors. (Secretary, Mr. L. Davis.)

**YORKE PENINSULA DISTRICT.**

(TO BUTE.)

**BRENTWOOD** (Average annual rainfall, 15.67in.).

Meeting held June 5th. Present: 17 members and five visitors. Mr. R. Anderson read a paper, "An Outsiders' Views on Farm Life."

A further meeting was held on July 3rd, when a paper, "Fallowing," was contributed by Mr. G. Boundy. The trophies won in the Southern Yorke Peninsula Fallow Competition were presented to Messrs. J. Darby, first, and — Bartram, second. (Secretary, Mr. G. L. Tucker.)

**PASKEVILLE** (Average annual rainfall, 15.67in.).

Twelve members attended the meeting held on July 8th. Mr. L. Moar read a paper, "Side Lines to Better Farming," which aroused a good discussion. Officers were elected for the ensuing year. (Secretary, Mr. J. Prouse.)

**PETERSVILLE.**

Eighteen members and visitors attended the Annual Meeting, which was held on July 8th. Following the reading of the annual report and balance sheet by the Hon. Secretary, Mr. A. G. Dutschke, of Ardrossan, the election of officers took place. The meeting then took the form of a social and dance, interspersed with vocal and musical items.

**SOUTH KILKERRAN.**

Eleven members attended the meeting held on July 8th. The Annual Report was presented and officers elected for the forthcoming year. (Secretary, Mr. H. C. Schrapel.)

**WAURALTEE.**

Meeting held April 8th. Present: 15 members and four visitors. A paper, "Plant Life," was contributed by Mr. Lethbridge.

Meeting held May 6th. Present: 13 members and visitors. Mr. M. Newbold read a paper, "Preparations for Seeding," and a report of the Conference of Yorke Peninsula Branches was given by Mr. Lethbridge. Seventeen members attended the meeting held on June 3rd, when a paper, "The Agent's Position," was contributed by Mr. Huicks. (Secretary, Mr. M. Newbold.)

**A. W. DOBBIE & Co.,**  
LIMITED,

99, Rundle Street, Adelaide.

**WESTERN DISTRICT.****CHANDADA.**

Mr. J. Carbery read a paper, "Fallowing," at the meeting held on June 20th, which was attended by 11 members. (Secretary, Mr. H. J. Chewings.)

**KAPINNIE.**

Meeting held June 27th. Present: 14 members. A paper, "Odd Jobs on the Farm," was contributed by Mr. S. Bulstrode. (Secretary, Mr. E. Wannan, Brimpton Lake.)

**KELLY (Average annual rainfall, 11.92in.).**

Meeting held June 14th at Mr. M. Martin's residence. A paper, "Holding the Young People on the Land," was contributed by Mr. J. Atkinson. (Secretary, Mr. W. Martin, Kimba.)

**KOPPIO (Average annual rainfall, 22.40in.).**

Mr. V. Gardner presided over an attendance of 12 members and three visitors at the meeting held at Mr. M. Gardner's residence on May 19th. Addresses were delivered by Messrs Orchard and Adams, of the Department of Agriculture. A Life Membership Certificate of the Agricultural Bureau was presented to Mr. H. Thompson. (Secretary, Mr. W. T. Gardner, White's Flat.)

**LAURA BAY.**

Mr. E. Barnett presided over an attendance of 17 members and visitors. Addresses were delivered by Messrs. W. J. Spafford and W. H. Brownrigg, of the Department of Agriculture. The meeting was held at the residence of Mr. W. Bewell on July 4th. (Secretary, Mr. W. Edson, Ceduna.)

**MALTEE.**

The annual meeting of the Branch was held on August 7th. There was a good attendance of members and delegates. The annual report was read and officers elected. (Secretary, Mr. E. Schwarz.)

**PALABIE.**

Meeting held July 9th at the residence of Mr. Rashleigh. Present: 13 members and four visitors. This was the inaugural meeting of the Branch, and the Secretary, Mr. E. H. Rasleigh, of Wudinna, read extracts from the Departmental Bulletin, "Handbook for Secretaries of the Agricultural Bureau."

**PINKAWILLINIE.**

The meeting of June 14th was held at the residence of Mr. S. Johnson, and was attended by 19 members and several visitors. The meeting took the form of a debate on the subject, "The Compulsory Pool v. The Open Market for Wheat." The team debating the claims of the open market were judged the winners. Supper was provided by the ladies. (Secretary, Mr. S. C. Johnson.)

**POOCHERA.**

The Annual Meeting was held on June 18th, and was attended by nine members. The annual report was presented and officers elected. Trophics won in the last year's wheat crop competition were presented to Messrs. G. Bockelburg and T. and J. McCormack. It was decided to place on record the services rendered to the Branch by Mr. Bohlin. (Secretary, Mr. F. R. Joy.)

**PYGERY.**

Meeting held July 8th. Present: 20 members. Mr. E. Edmonds read a paper, "The Cost of Production." (Secretary, Mr. A. Day.)

**ROBERTS AND VERRAN.**

Mr. G. Gordon presided over an attendance of 13 members and visitors at the meeting held on July 9th. An instructive paper, "Fodder Conservation," was contributed by Mr. M. Masters. (Secretary, Mr. C. M. Masters, Verran.)

**SMOKY BAY (Average annual rainfall, 10.61in.).**

The Hon. Secretary, Mr. K. Harrison, read a report showing the work performed by the Branch during the past year at the Annual Meeting, which was held on July 5th. Officers were elected and a programme of meetings arranged.

**TARAGORO.**

Eleven members attended the meeting held on July 10th, when an interesting paper, "Fallowing," was read by Mr. C. Hoffrichter. (Secretary, Mr. T. Winters, Cleve.)

**YADNARIE** (Average annual rainfall, 14.09in.).

Meeting held July 8th. Present: eight members. An instructive paper, "Fences," was read by Mr. E. Spriggs. (Secretary, Mr. C. J. Deer, Cleve.)

**YALLUNDA** (Average annual rainfall, 18in. to 19in.).

Meeting held June 10th. Present: 10 members. Mr. H. D. Adams (District Agricultural Instructor) delivered an address, "Working the Soil." (Secretary, Mr. R. P. Cabot, Yallunda Flat.)

**EASTERN DISTRICT.****(EAST OF MOUNT LOFTY RANGES.)****BERRI.**

Twenty members and ten visitors attended the Annual Meeting, which was held on July 7th. The annual report was presented, and officers elected. In appreciation of the valuable work performed in the interests of the Branch, Mr. W. R. Lewis, who has held the office of Secretary for 18 years, was presented with two upholstered chairs. (Secretary, Mr. R. Johnson.)

**BLOCK E.**

July 7th.

**ANNUAL PRUNING COMPETITIONS.**—The Branch held its Annual Pruning Competitions on Monday, July 7th. The tree pruning was held on Mr. L. A. White's block. Only three competitors entered this section. The trees selected had been pruned by the same competitors last year. The judges were Messrs. P. John and C. Pappin Smith, who remarked that the tree pruning showed a marked improvement on last year's, and faults mainly were no provision made for re-furnishing in the peach, weakness of leaders in the pear,

**THE SUNSHINE HEADER HARVESTER**

**HARVESTS ALL THE GRAIN POSSIBLE!!**

**— FROM ALL CLASSES OF CROPS!! —**

Sizes—6ft., 8ft., 10ft. cut.

Works equally well in light or down and tangled crops.

Price, Terms, and Illustrated Catalogue on application.

**H. V. McKAY Pty. Ltd.,** 95-97, North Terrace,  
**ADELAIDE.**

and overcrowding of fruit spurs in some instances in the apricot. The results in the trees were:—M. Pethick, first, 254 points; A. R. Nenke, second, 252 points; and H. B. Davis, 244 points. In the afternoon the vine competition was held on Mr. T. J. Hendrick's property, and was much better contested. The following are some of the judges's remarks:—Currants—Strong spurs cut too short, weak spurs left too long, too many three bud spurs, and spurs crowded. Sultanas—Number 1 cane (nearest to crown of vine) should go to bottom wire, and No. 2 to the top wire, this to keep fruit wood back to near the centre of vine; too many fractured canes; old wood not cleaned up; canes choked, bent too sharply on wire; water shoot and spurs underneath; too severe and too much saw; water shoot left in centre of vine; too many spurs and extended from frames; never leave spurs beyond canes. Gordos—Weak spurs too long, and spurs crowded; cut weak spurs back to one bud; too many spurs, and saw cuts too deep; three-bud spurs not wanted; saw cuts should be cleaned; too many base buds. The competitions were carried out under the new rules, which now include 10 points for time. The results of the vine section were:—M. Pietsch, 308 points; M. Pethick, 305½ points; A. R. Nenke, 291½ points; T. Hendrick, 289½ points; B. Jones, 281½ points; R. Falkner, 273½ points; H. Newstead, 263½ points; H. B. Davies, 259 points; W. Giles, 255½ points. (Secretary, Mr. H. B. Davies, Renmark.)

### BOOLGUN.

July 10th.—Present: 17 members and two visitors.

**SHEEP ON THE FARM.**—Mr. A. McGowan read the following paper:—"The most suitable class of Merino sheep for the mallee is a medium or strong to medium wool sheep. The fine wool Merino has a tendency to weaken and go down on the back. The strong wool Merino is all right, except that its fleece is inclined to become harsh and dry in mallee country. The medium or strong to medium wool Merino, with careful breeding, will produce a profitable and attractive fleece. In most cases flocks are classed by taking out the fats for market. The best method to adopt for classing is on a commercial basis, or for age. Fat sheep in most cases carry better fleeces than out-of-condition sheep. Ewes with loose, open wool, light, and small fleeces of very greasy nature, small and aged ewes should be taken out. The drawing of the teeth of a broken-mouthed ewe while there is plenty of green feed about will improve the ewe and give her a longer life. Sheep must be kept on good feed to produce a good animal. Shortage of feed means a weedy sheep lacking in quality and type. (Secretary, Mr. J. Palin.)

### BOWHILL (Average annual rainfall, 12in.).

July 7th.—Present: 27 members.

**BENEFITS OF THE AGRICULTURAL BUREAU.**—The following paper was read by Mr. G. Seidel:—"Benefits to be gained by farmers and all primary producers from activities connected with the Bureau can be classed directly and indirectly. We have an up-to-date Department of Agriculture in South Australia, and the South Australian farmer is not far behind in this respect, and the Bureau is described as the connecting link between the department and the farmer and producer generally, and is to-day recognised as being directly responsible for creating a wider interest among the producers to avail themselves of the result of the many experiments that have been tried out and proved a success. Without the advice of these experts, who have made a life study of the problems of production from the soil, farmers and producers would not be able to get such good results from the labor and capital put into the land. The Department of Agriculture in South Australia has connected with it experts in wheat and all cereal production; the dairyman has his expert; wool, fruitgrowing, poultry, all other livestock, and every line of activity in connection with agriculture. Any member of a Bureau who is confronted with a problem that he does not understand can get advice from these experts through the Bureau free of charge. This is indeed a privilege which is often passed over rather lightly. I have heard it said by some farmers that their practical experience over a period of 20 years or more should be sufficient and just as good as listening to a lecture by an agricultural instructor. Those same men are to-day using super and various recommended methods of pickling to prevent smut and sowing rust-resisting wheats. They do not seem to realise that it is only through scientific research and tests conducted over many years that has established the fact that by using super and selecting seed and handling it in the manner advised by these men who have successfully overcome any disability through conducting test after test that yields have increased and diseases at least partially wiped out. The average producer knows that he still has a lot to learn. He is constantly up against some problem, and although by practical experience he is certainly gaining knowledge there are many occasions when he is perplexed and will welcome expert advice. By becoming a live member of the Bureau he has the privilege of having valuable lectures by experts practically carried to him, and on other occasions when meeting with his fellow-producers we discuss each problem as it comes up, and many good ideas are exchanged

which must be beneficial to all concerned. Then he is in the privileged position to take an interest in the various crop competitions that are conducted in different districts throughout South Australia. The value of these competition cannot be over-estimated. They tend to increase average yields and create a rivalry which is beneficial, not only to those directly concerned, but to the whole of the producing community and the State. It has been proved that up-to-date working of fallow has made it possible to grow good crops on a low rainfall where before the improved method of working the fallow were put into operation the result was complete failure on the same rainfall. Fallow competitions are beneficial undoubtedly, and it is at meetings of the Bureau where these subjects are fully discussed. South Australia, in common with many other parts of the world, is passing through an economic depression, and many and varied are the reasons given for the present state of affairs. South Australia is dependent mainly on her primary production for her wealth. Then a discussion by members of an Agricultural Bureau on the economic situation is certainly not out of place. Such a discussion on what effect the universal use of the tractor on the farm in place of the horse has had on the general cost of production, whether it is an economically sound proposition to make money out of the South Australian soil and send it out of the country to pay for tractors and petrol. The primary producer is being looked to to-day to play a prominent part in levelling things up. I think he realises the position, and must study very closely his part in connection with the cost of production and the best way to distribute the results of his labor. This is a good subject for discussion. Then we have the pooling question, undoubtedly a very important one to the farmer. Advice to new members. It does not matter how old you are or how much experience you have had, you can keep on learning, sometimes from the young man who is a keen observer. To the younger members, do not be afraid to express an opinion on any subject. You will never succeed if you do not try. Remember that your Chairman and Secretary cannot make a thorough success of this Branch unless we all stick to the job. Some of the meetings will be a little slow. Then your job is to assist." (Secretary, Mr. M. Baeks.)

#### KULKAWIRRA.

July 15th.—Present: 12 members.

**SHEEP ON THE FARM.**—Mr. C. Robin read the following paper:—"For the purpose of this paper it will be assumed that shearing time is the end of the sheep year. When the flock has about a month's growth of wool the sheep should be dipped. Dipping not only destroys lice and tick, but acts as a check on the maggot trouble. Flockowners should also note that dipping is compulsory. A second dipping is seldom necessary in this district. During the spring months, blowflies are particularly active, and sheep which are unhealthy are liable to be struck. Lambs and hoggets also seem to be more liable to be struck than healthy grown sheep. The safest and most convenient preventive for lambs is to mix some arsenical sheep dip (about 10 times ordinary dipping strength), pour it into a shallow dish, and sit the lamb in it until the hindquarters are saturated. It is sometimes necessary to spray the whole flock. The best preventive against the maggot trouble is to keep the flock healthy, and to do this, divide up the pastures so that the sheep can be moved often. In new mallee country rubbishy herbage seems to predominate, and if a flock has a big area to wander over, the animals soon eat out the best nutritious plants and are gradually forced to eat the poorer herbage; this leads to digestive disorders and other troubles soon follow. Where new settlers have large areas of stubble on which they wish to run sheep, they will be able to keep a much larger flock if they made use of temporary fences for subdividing. To drill superphosphate and oats on the stubble is a sound payable proposition; also when rain falls in the autumn after a dry spell, it will pay to hand feed the flock with oats or chaff for two or three weeks until fresh green feed has got sufficient growth to feed the sheep. May is usually quoted as the proper month for lambing, but after the run of dry summers we have had for some time, I question whether it is the best for this district. April, May, and June have for some years past been our most difficult time for feed and our winters are not hard; also, if lambing comes after seeding, the flockowner can give more time to the flock. The flock should be visited every day during lambing. Young ewes are often touchy and will not let the young lambs suck, consequently they die of starvation. The flock needs a great deal more attention than most people seem to think, and to get good results takes time, labor, and some expense. (Secretary, Mr. H. Elliot, Karoonda.)

#### LAMEROO (Average annual rainfall, 16.33in.).

Mr. J. Koch presided over a good attendance at the meeting held on July 12th. The annual report and balance-sheet were presented, officers elected, and a programme arranged for the ensuing year. (Secretary, Mr. R. Koch.)

**MONARTO SOUTH** (Average annual rainfall, 14in. to 15in.).

Twenty-five members attended the meeting held on June 21st, when an interesting paper, "Careful Farm Management," was contributed by Mr. E. Zeunert. (Secretary, Mr. C. Altmann.)

**MOORLANDS** (Average annual rainfall, 14.76in.).

Meeting held May 14th. Present: 10 members and six visitors. Mr. P. H. Suter (Senior Dairy Instructor) delivered an address, "The Dairy Cow."

A further meeting, attended by eight members and visitors, was held on June 18th, and took the form of a "Question Box."

Meeting held July 9th. Present: 11 members and visitors. Mr. E. Herbert contributed a paper, "Handy Jobs on the Farm." (Secretary, Mr. L. Orloff.)

**MURRAY BRIDGE** (Average annual rainfall, 13.84in.).

Meeting held June 18th. Present: 14 members. Mr. E. Leishman (District Horticultural Instructor) gave an address, "The Care of the Orchard."

The meeting held on July 16th was attended by 14 members and visitors from the Brinkley Branch, who read the following papers:—"Increasing Farm Production," Mr. Pearson; "A Woman's Place on the Farm," Mr. Humphris; and "Government Experimental Farms," Mr. Rust. (Secretary, Mr. S. Jones.)

**PINNAROO** (Average annual rainfall, 14.94in.).

Meeting held May 21st. Present: 23 members and five visitors. Addresses were delivered by Messrs. W. C. Johnston and R. L. Griffiths, of the Department of Agriculture.

**PINNAROO WOMEN'S** (Average annual rainfall, 14.94in.).

Meeting held July 4th at Mrs. W. Davis' residence. A large number of members and visitors were present, when a Pruning Demonstration was given by Mr. E. Leishmann (District Horticultural Instructor). (Secretary, Mrs. F. Atze.)

**RAMCO.**

April 15th.—Present: Nine members.

**COWS AND PIGS AS AN ORCHARD SIDE LINE.**—Mr. J. Boehm read the following paper:—"Cows are a necessity on the orchard, especially where there are small children. If £10 to £12 is available for the purchase of a cow, select a good young animal. If a family of about six or seven buys milk and butter it would cost about 11s. or 12s. per week, so that in about five or six months the cow would be paid for. A good cow which gives 5galls. to 6galls. of milk a day pays for herself in a short time. A cow giving on an average of 3galls. per day would keep a family, as mentioned above, going for 10 months at least. The value of milk and butter for the 10 months would, at the present price, amount to £24. I have a cow which gave 8galls. of milk per day when first in milk, and after 22 months still gave 2galls. per day. People who object to the keeping of a cow on an orchard usually state that it is difficult to obtain food for the animal. Every orchard has the opportunity of growing lucerne, which is the best feed for a milking cow. In winter, cocky chaff with a little bran is a good and cheap form of fodder. In good seasons cocky chaff can be bought very cheaply. The cost of chaff and bran at 3s. 6d. per week are based on the keeping of my cow for 22 months—total for 22 months' feed, £8 8s.; cost of cow, £5; expenditure, £13 8s. Income for 22 months: value of milk, £50 16s.; value of cow, £18; total, £68 16s.; credit balance, £55 8s. With the separated milk pigs can be raised. Pigs are also very profitable. Twelve months ago I bought two small pigs at 12s. each. I kept them just 12 months and sold one at £5 5s.; the other I killed for home use. It weighed 240lbs., which at 6d. a pound amounts to £6. The pigs cost nothing to feed; all they received was milk and waste fruit, &c." Mr. C. Boehm agreed that such sidelines were profitable where there were people to attend to them, but when one had all the work to do, then it could not be done satisfactorily. After working all day, one could not do such work. If cows were kept, then certainly pigs were almost a necessity, but he considered they were too far away from a market. The writer had not allowed for labor; if that were added, then profits were not so great. Mr. R. Stanley said with children to help, cows and pigs were certainly a good sideline. A good cow kept in the yard and fed was a paying proposition and no trouble. He thought it might be profitable to buy a number of young pigs as suckers, put them into a Gordo vineyard, say one acre, and let the sucker do the picking. Would they not be worth more than Gordos at present?

A further meeting was held on May 12th, there being present seven members. Discussing the question, "Is it advisable to pull out Gordos to plant another variety?"

# THE IMPLEMENT CO.

Offer a Complete Line of

## Harvesting Machinery

Don't risk a whole year's work when you can ensure against loss by getting light running, easily handled harvesting machinery on which you can always depend to harvest and market your crop. You will find in the Implement Co. line the finest materials and workmanship—and, what's best of all, years of satisfactory service.

**HORWOOD-BAGSHAW  
"GASTON" HEADER.**

The simplest, easiest running, and most effective Reaper Thresher in Australia. Sizes, 8ft. and 10ft. cut. This machine has fully earned its name—"The Better Built Header."

**HORWOOD-BAGSHAW  
"ILLMAN" STRIPPER.**

The Horwood-Bagshaw "Illman" Stripper is the result of many years close attention to the requirements of Mallee Farmers, and we are confident in offering this machine to fill the demands of the most exacting user. Made in 8-ft., 9-ft., and 10-ft. sizes.

# THE IMPLEMENT COMPANY

**BANK AND BLYTH STREETS, ADELAIDE.**

Mr. F. Lewis said it was often stated that if vines did not produce 2 tons to the acre, root them out and plant lucerne; he did not agree with that. In his opinion Gordos at Ramco paid. "A plot of  $\frac{1}{2}$  acre of currants was not much good; they were going out, though apricots just above them were all right. A lot of chickweed grew amongst the vines. Is it advisable to pull out these currants and plant anything else?" It was suggested that lime might be tried on the ground or it might be advisable to plant trees, say apricots, as they seemed to do well. "Would sheep interfere with orange trees if shut in a grove?" One member said lambs would eat young shoots, but another had read an article advising the running of sheep, as they manured the soil and choked weeds. "Which is more profitable—to put 2 acres of high land into wheat and oats or Sudan grass?" Mr. Lewis said oats could be sown early and the Sudan grass in October.

#### TULKINEARA.

Meeting held July 17th at the residence of Mr. F. Vardon. Present: six members. Mr. P. H. Suter (Senior Dairy Instructor) addressed the meeting. (Secretary, Mr. F. Vardon.)

#### WILKAWATT WOMEN'S (Average annual rainfall, 16in. to 17in.).

Meeting held July 15th. Present: 10 members and visitors. Mrs. J. Steer gave an interesting and instructive afternoon. She exhibited cakes, jellies, dried vegetables, and recipes for jam, and gave numerous labor-saving household hints. (Secretary, Mrs. A. Oram.)

### SOUTH AND HILLS DISTRICT.

#### BALHANNAH.

Meeting held July 11th. Present: 10 members. The Hon. Secretary (Mr. H. A. Spoehr) presented the annual report and balance-sheet, and officers were elected for the ensuing year.

#### BLACKHEATH.

Meeting held June 12th. Present: Seven members and visitors. A paper, "The Dietetic Value of Cereals," was read and discussed. (Secretary, Mr. E. H. Paech, Rockleigh.)

#### CURRENCY CREEK.

The meeting held on April 14th took the form of a "Question Box," and was attended by eight members.

Meeting held June 16th. Present: 14 members. A paper, "Varying Milk Tests," was contributed by Mr. D. Gordon.

The Secretary (Mr. D. J. Gordon) reports that there was an excellent attendance of members and visitors at the meeting held on May 15th, when Mr. W. J. Spafford (Deputy Director of Agriculture) delivered an address, "The Growing of Cereals."

#### GUMERACHA (Average annual rainfall, 33.54in.).

Meeting held July 7th at the residence of Mr. G. Randle. Present: 14 members. Mr. A. Garth gave an address, "Digestion." (Secretary, Mr. L. W. Wise.)

#### HARTLEY (Average annual rainfall, 15in. to 16in.).

Mr. W. Bermingham presided over an attendance of 15 members at the meeting held on June 11th. The following papers were read and discussed:—"Wheat Varieties," Mr. F. Wundersitz; "Peas as a Side Line," Mr. F. Pope.

Meeting held July 9th. Present: 14 members. The annual report was presented by the Secretary, Mr. H. Harvey.

#### KANGARILLA.

Meeting held July 11th. Present: 13 members and 16 visitors. Mr. A. H. Robin, B.V.Sc. (Government Veterinary Officer), delivered an address, "Ailments of the Dairy Cow." (Secretary, Mr. T. O. Golder.)

#### LONGWOOD (Average annual rainfall, 37in. to 38in.).

Meeting held July 5th at the residence of Mr. W. Nicholls. Present: Mr. W. Hughes (Chair) and 12 members. Members were given the opportunity of inspecting the Koolin Works. Afternoon tea was provided by Mrs. Nicholls. (Secretary, Mr. J. R. Coles.)

---

McLAREN FLAT.

On June 19th a representative of the Vacuum Oil Company gave an address, illustrated with moving pictures, "Oil and its Products." There was a large attendance of members and visitors.

On June 21st the fourth Annual Juvenile Pruning Competition was held in Mr. J. Ingoldby's vineyard. Forty-eight competitors entered, the winners of the various sections being Masters J. Dowdell, W. Ward, T. Penny, D. Hunt, and C. E. Air.

The annual meeting was held on July 10th, there being present 20 members. The annual report and balance-sheet were presented, and officers elected for the ensuing year. (Secretary, Mr. A. Bruce.)

---

## MOUNT COMPASS.

The Annual Meeting was held on June 3rd, and was attended by a large number of members and visitors. Mr. H. B. Barlow (Chief Dairy Instructor) delivered an address, "Bacterial Cultures in Milk." Officers were elected.

Mr. A. Kidman presided over an attendance of 28 members. Mr. Jefferies gave an address, "The Handling of Farm Stock." (Secretary, Mr. J. R. Black.)

---

## MOUNT PLEASANT (Average annual rainfall, 27.38in.).

Meeting held June 13th. Present: Nine members. Mr. V. Tapscott read an instructive paper, "Fodder for Stock."

The annual meeting was held on July 11th, and was attended by eight members. A report of the year's work was presented and officers elected. (Secretary, Mr. D. Stow-Smith.)

---

## PORT ELLIOT (Average annual rainfall, 20.05in.).

The annual meeting was held on July 19th, when there were present 18 members. The annual report and balance-sheet were presented and adopted. (Secretary, Mr. A. E. Lowe.)

---

## SCOTT'S BOTTOM.

The meeting of July 5th was held at the residence of Mr. R. Thorpe, and was attended by 11 members. Several questions were submitted to be forwarded to the Department for a reply. Other matters of local interest were discussed. (Secretary, Mr. E. Atkinson, Cherry Gardens.)

---

## SHOAL BAY.

Twelve members attended the Annual Meeting, which was held on July 8th. The Hon. Secretary (Mr. H. T. Bell, of Wisanger, Kangaroo Island) presented the annual report and balance sheet, and officers were elected.

---

## SPRINGTON.

Mr. W. Roesler presided over an attendance of 15 members. Mr. L. Brownsea read an instructive paper on his experiences since his arrival in South Australia. (Secretary, Mr. E. Brokate.)

---

## STRATHALBYN (Average annual rainfall, 19.22in.).

The annual meeting was held on July 8th. There was a very large attendance of members and visitors, including Mr. H. N. Wicks (Vice-Chairman of the Advisory Board of Agriculture), delegates from other Branches in the Southern District, and the Mayor of Strathalbyn (Mr. F. W. Elliott). Vocal and instrumental items were contributed, and the evening concluded with a supper provided by the ladies. (Secretary, Mr. F. W. Allison.)

---

## TWEEDVALE (Average annual rainfall, 36.08in.).

Meeting held May 29th. A large number of members and visitors attended the meeting, when an illustrated address, "Motor Transport," was delivered by an official of the Royal Automobile Association.

On June 5th a lecture, illustrated with moving pictures, was delivered by a representative of the Vacuum Oil Company.

The Annual Meeting was held on June 10th. There was a large attendance of members and visitors, including delegates from neighboring Branches and Members for the District. Supper was provided by the ladies, after which a dance was held. (Secretary, Mr. A. B. Schapel.)

# CROWN LANDS.

---

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Secretary for Lands, Box 293A, Adelaide.

---

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

---

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

## AGRICULTURAL VIEWS AND COMMENTS.

### Feeding Values of Wheaten, Oaten, and Barley Hay.

In reply to a question submitted by the Snowtown Branch of the Agricultural Bureau, Mr. W. J. Spafford (Deputy Director of Agriculture) states that on analyses barley hay is a good deal better than either wheaten or oaten hay ton for ton, but the high proportion of beard carried by barley hay, makes it troublesome to farm livestock. Hays made from the three cereals when cut at flowering time, and when reduced to the same moisture content, can be compared as follows:—

| Hay.          | DIGESTIBLE NUTRIENTS. |          |      |                 |        |                    |
|---------------|-----------------------|----------|------|-----------------|--------|--------------------|
|               | Moisture.             | Protein. | Fat. | Carbo-hydrates. | Fibre. | Starch Equivalent. |
|               | %                     | %        | %    | %               | %      | %                  |
| Wheaten ..... | 10.0                  | 4.0      | 0.4  | 30.0            | 12.9   | 31.4               |
| Oaten .....   | 10.0                  | 5.3      | 1.6  | 25.4            | 18.2   | 32.5               |
| Barley .....  | 10.0                  | 4.3      | 0.9  | 34.7            | 18.3   | 42.8               |

The starch equivalent figures show that if no trouble was to be experienced from the strong beard on the barley hay about 3cwts. of barley hay would be equivalent to about 4cwts. of either wheaten or oaten hay. For anyone who is prepared to show the necessary attention to the inside of the mouths of animals to be fed upon it, barley hay can be recommended for farm livestock. It must be remembered when considering the growth of this hay that, although barley makes bulky crops, as a rule it "dries out" like any other hay. To reduce the trouble due to the presence of such a tough beard, barley should be cut at a greener stage than is usual for wheat or oats.

### Limestone Sawdust for Pastures.

Mr. W. J. Spafford (Deputy Director of Agriculture) states that in 1926 one of the plots in the Natural Pasture Improvement Experiments was dressed with 1 ton of Mount Gambier limestone sawdust per acre, and each year receives an application of 1cwt. superphosphate per acre. The results secured in comparison with other plots started at the same time are as follows:—

#### Grazing Results, Kybybolite, 1926-1929.

|                                                             | Sheep per Acre per Year. |       |       |       |        |
|-------------------------------------------------------------|--------------------------|-------|-------|-------|--------|
|                                                             | 1926.                    | 1927. | 1928. | 1929. | Means. |
| 1 ton Limestone Sawdust (1926), 1cwt. Super. annually ..... | 1.99                     | 1.86  | 2.54  | 2.52  | 2.23   |
| 1 ton Gypsum (1926), 1cwt. Super. annually .....            | 0.98                     | 1.50  | 2.08  | 1.95  | 1.63   |
| 180lbs. Super. annually .....                               | 1.27                     | 1.34  | 2.06  | 2.15  | 1.70   |
| No manure .....                                             | 0.99                     | 0.97  | 0.58  | 1.05  | 0.90   |

It will be noticed that there has been a marked beneficial effect on the grazing capacity of the pasture treated with the limestone sawdust against super alone, and against gypsum and super. If it is intended to use this sawdust as a top-dressing, it must be remembered that it does not replace superphosphate but should be used in conjunction with it.

### Storing Hams.

Mr. H. B. Parlow (Chief Dairy Instructor) has forwarded the following advice on the storing of hams to an inquirer at Mannum:—See that the hams are well dried out, otherwise mould is likely to develop. To keep hams for a lengthy period they require heavier salting. Dip the calico bags in a good creamy paste of whitewash, and immediately tie it round the hams. Prevent the wash from getting inside the bags, if possible.

### **Sulphate of Ammonia v. Super for Barley for Greenfeed.**

The Deputy Director of Agriculture (Mr. W. J. Spafford) has informed the Farrell's Flat Branch of the Agricultural Bureau that under South Australian conditions no proper comparison can be made between the effects of dressings of superphosphate and sulphate of ammonia for barley crops, because our soils are so deficient in phosphorus that we must use a phosphatic manure to grow normal barley crops. In some locations a comparison could be made between the effects of using superphosphate alone and a mixture of superphosphate and sulphate of ammonia as, for instance, where intense culture is being practised and bare fallowing the land is not usual.

In such a case there is every chance that the mixture will give a better economic return of greenfeed than will superphosphate alone. On our ordinary farm land, however, the position is quite different, and in all probability superphosphate alone is the better of the two forms of manuring. A mixture of 1cwt. superphosphate (45 per cent.) and  $\frac{1}{2}$ cwt. sulphate of ammonia will cost about 12s., and this amount of money will purchase nearly 2 $\frac{1}{2}$ cwts. of superphosphate, and it is doubtful whether 12s. worth of the mixture would give greater returns in your district than superphosphate of the same value.

---

### **Blue Lupins.**

"Are New Zealand Blue Lupins fed to cows as fodders?" is a question recently submitted to Mr. W. J. Spafford (Deputy Director of Agriculture), who states that we do not know to which of the Blue Lupins the term New Zealand has been attached, but most of the Blue Lupins are only of value as a foodstuff for livestock after the seeds are ripe and have been "shot" on to the ground. Animals—and particularly sheep—pick up the fallen seeds and do well on them. The growing parts of the hairy blue lupins are disliked by farm animals, and, as a matter of fact, they will not touch the plants unless almost starving.

---

### **Control of Red Spider.**

"It is usual to treat crops affected by red spider with kerosine emulsion or tobacco wash in the winter, and with sulphur in the summer," is a reply given by Mr. W. J. Spafford (Deputy Director of Agriculture) to an inquiry from the Yeelana Branch of the Agricultural Bureau. Great care must be taken to make certain of spraying all parts of the plants, as the mites quickly breed up again if any are missed. The Department of Agriculture has published a leaflet by Mr. G. Quinn on "Common Pests and Diseases of Fruit Trees and Vines," in which will be found the formulae for making the spray mentioned.

---

### **Lucerne Growing.**

Replying to a correspondent at Black Hill, who sought information as to the best methods of establishing a plot of lucerne, the Deputy Director of Agriculture (Mr. W. J. Spafford) says in most parts of the State it pays to bare-fallow the land before seeding it to lucerne, because less trouble is experienced with weeds, but provided the land is reasonably free from weeds, this is not absolutely necessary. It is essential, however, that the soil preparation be very thorough, and the surface must be worked down to a fine tilth before seeding. Seeding should be done in April-May or September, and the seed must not be drilled in unless the soil is sufficiently moist to make certain of a good germination. The seed can be mixed with superphosphate, and be drilled in with an ordinary seed drill, remembering that the *seeding must be very shallow*, and the seed should not be mixed with the superphosphate for *more than four hours* before being drilled into the soil. If to be irrigated, 15lbs. to 20lbs. of seed per acre should be used, and 2cwts. of superphosphate can be put in at the same time. The first cut should be made as soon as the growth is high enough to be properly cut, and the mixture of lucerne

and weeds secured by this cut should be carted off the land. The sooner the first cut is taken the sooner will the lucerne crop control the weeds. The lucerne crop should be thoroughly cultivated each year in July or August, and receive an application of about 2cwt. superphosphate per acre at the same time.

---

### Soursobs.

“What means can be adopted to exterminate soursobs and magnesia patches which are increasing in area?” This question was received from the Talia Branch of the Agricultural Bureau. The following reply has been supplied by Mr. R. C. Scott (Supervisor of Experimental Work):—On account of their bulbing nature it is very difficult to exterminate soursobs over any area. By good cultivation and comparatively late seeding they can be kept in check so far as crops are concerned. Seeding should be delayed until this weed has germinated freely, and the land well tilled prior to drilling. On smaller areas it appears possible to destroy soursobs by spraying with solution of 100lbs. sodium chlorate to 100galls. of water to the acre, when the plants are in full bloom. As this is expensive it is impossible for farm lands, but is of value for gardens, &c.

A low annual rainfall and high summer temperatures are factors affecting the formation of salt of magnesia patches. The former is insufficient to wash out the soluble salts which accumulate in the upper soil layers as the moisture is evaporated in the summer months. In the first place, if the contour of the land permits, drains should be run through the affected patches leading to some natural watercourse in order that heavy rain may tend to drain away the salts dissolved. Secondly, anything which will shade the ground, thus checking evaporation, will reduce the accumulation of salt. An application of farmyard manure, straw, &c., is of assistance, but the object should be to make this protecting cover consist of a crop. In order to place the soil in the best possible condition for young plants to develop, it should be ploughed deeply late in the autumn and the furrow slice completely inverted so that the salt is buried and sweet soil left on the surface. The opening rains will tend to further sweeten the land and wash the salt deeper, thus improving the chance of a good germination of any seed planted. Late in the season a quick growing crop should be sown, of which barley is probably the most suitable, because of its earliness and resistance to salt. The straw should not be burned, but left to cover the soil. This practice should be continued again in the following year.

---

### Lambs for Export.

Replying to a question, “What would the live weight of a lamb be to dress 36lbs.?” which was asked by the Kangarilla Branch of the Agricultural Bureau, Mr. R. C. Scott (Supervisor of Experimental Work) says, as a general rule, a lamb dressing 36lbs. would have been approximately 72lbs. live weight. However, the shrinkage on dressing will vary from about 48 to 54 per cent., according to the type of lamb. A short-legged, thick-set type will lose the lesser amount, whilst the more it approaches the Merino type the greater will this loss be. Experiments conducted at Roseworthy College some years ago showed that pure-bred Merino lambs, averaging 73.30lbs. live weight, gave a mean dressed weight of 33.07lbs., or a shrinkage of 54.88 per cent. On the other hand, lambs from half-bred longwool ewes by Southdown rams, averaging 74.70lbs. live weight, yielded 37.94lbs. on dressing, or a loss of 49.22 per cent.

---

### Blindness in Calves.

A correspondent at Gladstone reports that calves from six months up to nine months of age, in good condition, with plenty of good food and water available, suddenly became blind and within 24 hours died. This inquiry was submitted to Mr. C. McKenna,

B.V.Sc., M.R.C.V.S. (Government Veterinary Officer of the Stock and Brands Department), who says the type of blindness described in the calves has been fairly common during the past 16 months and has been reported from various parts of the State. The ages of the affected calves vary from one to nine months; the majority however, are two to four months. Usually the blindness develops gradually, and in every case both eyes are affected. They become glassy, have a staring appearance, and are a bottle-green color. No inflammatory changes have been observed. In some cases diarrhoea is present. Loss of condition is frequently observed. Some affected calves have fits or convulsions. Again, others hold their heads continually on one side or turn around in circles. From the observations made, we are inclined to think that the condition is due primarily to the lack of certain vitamin. This substance is usually obtained by the cow from green feed and passed on to the calf in the milk. It is not present in dry feed. For over the past two years the State has experienced poor seasons and long-continued dry periods. This has meant an absence of green feed in the ration over a long time (in one district this period was seven months). This has resulted in a deficiency of this particular vitamin. It is very probable that with a return to normal seasons this disease will become rare. Cases of affected calves having recovered their sight have not been reported, and treatment which has been tried has not been successful. Preventive measures advised are:—Firstly, the supplying of green feed to the cows during the dry periods of the year. Even in the dry areas a small area of green feed, especially lucerne, can usually be grown. Secondly, the feeding of cod liver oil to the calves. Cod liver oil contains the particular vitamin we have referred to. The following quantities are suggested:—1oz. up to the fourth week; 2ozs. up to the sixth week (1oz. equals two tablespoonfuls); 3ozs. up to the eighth week and over. The cod liver oil should be put in the bottom of the bucket and the skim milk gradually added whilst the mixture is kept stirred.

#### **Horse, Barb-wire Wound.**

Reporting that a horse had been injured with barb-wire and that the wound had become fly-blown, a correspondent at Wanbi sought information as to the best treatment to adopt to effect a cure. The inquiry was submitted to Mr. R. H. F. Macindoe, B.V.S., M.R.C.V.S., Deputy Chief Inspector of Stock, who states that maggots may be removed by injecting into the wound oil of turpentine, but it will not kill them. The following treatment is suggested:—Clip hair around the wound and wash with warm water and soap. Then inject a little oil of turpentine right into the bottom of the wound and search with a pair of forceps (made by bending a piece of hoop iron and filing it down to a size small enough to enter the wound) for maggots which may be deep-seated. Use the oil of turpentine two or three times a day until you are certain that all maggots are removed and then treat by injecting a lysol solution (one tablespoonful to a pint of water) twice a day and plug slightly with a small piece of cotton wool. If the wound is discharging, smear beneath the entrance to wound with vaseline.

#### **Dry and Wet Ploughing.**

The Millendilla Branch of the Agricultural Bureau submitted the following question:—“Is fallow ploughed dry and worked down when wet as good as if the ploughing was delayed until the time of giving the first cultivation to the dry ploughing?” Reply:—Provided that the “dry” ploughing is done early in the season, that is to say, before the heavy rains are finished, better results will be secured as against waiting for the soil to become wet before ploughing. The longer stirred land is exposed, the more plant food liberated, and if the ploughing is done in the autumn or winter enough rain can be expected to again consolidate the soil. (Reply by Mr. W. J. Spafford.)

Now for the Harvest-

Stocks of CROSS Power Kerosene and GOLDEN SHELL Oil are available everywhere to assist you in the rapid, economical and efficient working of your tractor during the harvest season.

PRODUCTS OF THE SHELL COMPANY LIMITED

**Weed Destruction.****BLACKBERRIES.**

The following inquiry was received from Echunga:—"I have read about sodium chlorate killing ragwort in New Zealand; as I have a lot of blackberries, would sodium chlorate kill them?" Reply.—Our experience with treating blackberries with sodium chlorate is that it kills all of the above-ground growth, and only a few weak shoots are sent up from the old crowns, and that a second application destroys most of these. We have been using a 5 per cent. solution, i.e., 1lb. of sodium chlorate in 2galls. of water, which is sprayed on to the plants so as to wet all the growth. After seeing the results of our original experiments at Williamstown the owner of the property immediately ordered 1 ton of the material for the destruction of this pest. Sodium chlorate is obtainable from the Hardie Trading Pty., Ltd., Currie Street, and from the Oresco Fertilisers Ltd., North Terrace. (Reply by Mr. W. J. Spafford.)

**Take-All.**

"What is the cause of wheat drying off two months after seeding, which usually occurs in small patches, and the wheat grows to a height of several inches, and can be pulled out with ease, having no hold on the soil with the roots. Why does this occur more on good or early fallow than on ground not so well worked?" This question was also asked by the Millendilla Branch. Reply:—When young wheat plants which die can be readily pulled out of the ground the trouble is usually due to "take-all," the excessive looseness of the soil encouraging the disease. On the first appearance of the trouble the land should be heavily rolled, or be packed in some way, when the chances are that an immediate improvement will be noticeable. The latter part of the question cannot be answered without having seen the different blocks of land. (Reply by Mr. W. J. Spafford.)

**Lime for Clayey Soils.**

The Beetaloo Valley Branch of the Agricultural Bureau asks:—"What quantity of lime should be applied to land of a red clayey nature in this district?" Reply.—To improve the mechanical condition of the red clayey land of your district at least 10cwts. of lime per acre should be used, but almost equal results will be secured at a much less cost, and without being such an unpleasant job if the same amount of seed gypsum is applied. It must be remembered when applying either lime or gypsum that they should not be ploughed in, but should be spread on the surface after the land has been ploughed and cultivated, and only harrowed in. Seed gypsum can be drilled into the cultivated land, but lime and flour gypsum must be broadcasted, because so little will run through the seed-drill, and they are applied very irregularly by his machine. (Reply by Mr. W. J. Spafford.)

**Experiments in Fruit Setting of Apple.**

During the past two years experiments have been carried out in Otago by the Horticulture Division with the object of determining the treatment which would cause strong-growing Delicious apple trees on rich alluvial soil to set their fruit satisfactorily. Several series of tests—manurial and pruning—were carried out.

Reporting on the work, Mr. W. K. Dallas states that the treatment which gave the best results was a normal pruning, combined with the application of sulphate of potash at the rate of 2lbs. per tree in the month of August in each of the two years. The trees set a crop which averaged 14 loose petrol cases per tree, as compared with an average of five loose cases in the other plots. The pruning consisted of a judicious cutting out of leaders where it was considered that there were too many in the trees, with the object of allowing more sunlight into the centre. The lateral growth was thinned out, and the remaining laterals shortened back from 14in. to 18in. in length. —(From *New Zealand Journal of Agriculture*, August, 1930.)

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

"E. H. H.," Wanbi, reports cow in milk 12 months, milk supply now falling off, low in condition.

Reply—You do not give any particulars as to what feed the cow has been getting, but in the absence of any symptoms indicative of disease, it is quite possible that being a heavy milker constantly over a long period, the ration is insufficient to keep her up in both milk production and condition, so that the former has been maintained at the expense of the latter. I would suggest that you feed her a bit more liberally, especially on concentrates, such as bran, oats, and linseed meal and see if any benefit results.

"F. E. C.," Balaklava, reports pony bad cough, coat very rough, urine thick.

Reply—The following treatment is suggested:—Stable pony and starve for 24 hours (allow water only). At the end of that period give the following drench:—Raw linseed oil, one pint; turpentine, four tablespoonfuls. Subsequently feed on good-quality chaff and bran and crushed oats and give a tablespoonful of Fowler's solution of arsenic mixed in a small damped feed night and morning for two weeks. During the period supply cut green barley daily.

"A. J. O.," Ceduna, has horse 13 years ago, off feed, signs of staggering after drinking and has swellings under belly.

Reply—Have the animal's teeth seen to if possible, and give the following drench:—Raw linseed oil, 1½ pints; turpentine, four tablespoonfuls, and repeat same in 10 days' time. Allow plenty of good green feed in the ration and supplement this with a little bran and good chaff. Give one tablespoonful of Fowler's solution of arsenic in the damped feed night and morning for a fortnight, and also have a supply of the following powders made up, each containing P. nux vomica, 1 dram; P. ferri sulph., 1 dram; P. radix gent., 1 dram. Give one powder night and morning half-hour after feeding. Mix the powder in a spoonful of molasses or honey to make a paste which can be smeared on the back teeth and tongue so that it will stick there and the animal will have to lick it down. The oedematous swelling under the belly should be well massaged regularly each day so as to break it up and assist its resorption. This will gradually take place as the animal regains its strength. Do not attempt to work the animal, but give it a spell.

"G. R. T.," Yurgo, has mare seven years old with large lump on shoulder.

Reply—The swelling should be treated by applying hot fomenta at frequent intervals. If any fluid can be detected as being present the swelling should be lanced at its lowest edge, so that these fluid contents can be evacuated. Subsequently, syringe the cavity out daily with weak antiseptic solution till the discharge stops and healing takes place. On no account should the animal be worked till the condition has cleaned up.

"H. W. C.," Mannum, asks cure for founder in young pigs.

Reply—If the pigs are kept away from the mother while she is being fed on the grain, so that they are not able to get any of it, the condition will right itself in them in a few days' time. A dose of 1oz. Epsom salts per sucker given to them either as a drench or mixed in a little thin slop will help if given early in the attack.

"E. A. R.," Tarnma, has cow very hard to milk.

Reply—If you can obtain a better cow I would advise you to fatten up the hard milker for the butcher. The only treatment you could try would be to dilate the teat with a "teat dilator." You will have to obtain this instrument from one of the Adelaide firms. When using it see that it is clean (boil for 10 minutes) and paint the teat orifice with tincture iodine before inserting it.

# An improved Ford Truck

**Increased strength  
and stamina from  
notable structural  
improvements**

*An Improved Ford 30-cwt. Truck undergoing tests in Geelong District (Vic.). At left is a test truck ready for inspection. Note sturdy steel torque tube and radius rods.*

*Underside view of a test truck ready for inspection.*

**THE FORD 30-cwt. Truck—**already famous for its Value far above the Price—has now been notably improved in strength and durability by im-

portant structural alterations. Its new torque-tube drive and sturdy rear radius rods give added safety, longer life, greatly improved performance under rough conditions and still lower operating costs to a truck which has already proved itself as possessing these essential qualities to an unusual degree.

**New Torque-tube Drive.**—The new heavy steel torque tube surrounds the driving shaft and transmits all driving thrust from the rear-axle housing to the heavy cross member of the frame. This relieves the rear springs of all but their normal function of cushioning the load, improves riding qualities, and lengthens the life of important chassis parts.

**New Radius Rods.**—The new sturdy steel radius rods support the torque tube in its function of carrying the driving thrust and maintain the rear-axle housing in perfect alignment under all conditions of road unevenness and sudden strain. They increase the Ford Truck's capacity for fine and lasting performance under unusually difficult conditions and driving abuse.

**Rigid Tests Prove Tremendous Strength.**—Exhaustive tests of the Improved Ford 30-cwt. Truck have covered thousands of miles over shocking roads and heavy tracks. The test trucks were deliberately abused in every way in which misuse could be experienced at the hands of roughest drivers. Gruelling haulage of heavy timber through deep sand and over open country, hauling heaped loads of gravel out of deep pits and over deeply rutted tracks, were endured day after day for weeks, without mechanical attention. On completion of the tests the closest inspection by Ford engineers revealed each mechanical and structural part in perfect condition.

## Features of the Ford Truck

*New Torque-tube Drive . . . New Rear Radius Rods . . . Four cylinder Engine, rated 24.03 horsepower, developing 40 brake horsepower at only 2200 revs. per minute . . . Aluminium Alloy Pistons . . . Direct, gravity-feed fuel system . . . Enclosed four-wheel brakes . . . Heavy cantilever rear springs . . . Wheelbase 131½ inches . . . Capacity 1½ tons . . . Standard body styles for every purpose . . . Easiest terms of payment under the New Ford Finance Plan.*

# NINTH ANNUAL REPORT OF THE TURRETFIELD DEMONSTRATION FARM (1929-30), INCLUDING DETAILED ANALYSIS OF MEAN FARMING COSTS (1921-30).

[By ARTHUR J. PERKINS, Director of Agriculture.]

## PART I.

### 1929-30 FINANCIAL TRANSACTIONS.

#### GENERAL SCHEME UNDER WHICH THE FARM HAS BEEN RUN.

The Turretfield Demonstration Farm has been run upon purely business lines since 1921, and it has therefore had to depend upon its own unaided revenue for nine successive seasons. In the latter connection, however, the Farm has been allowed overdraft rights up to £2,200, upon which 6 per cent. interest has been paid on monthly balances. On the other hand, in addition to interest on overdraft, the Farm has paid annually into the State Treasury the equivalent of rent on land and interest on original Floating Capital, less repayments of original loan which may have been made. During the seven initial seasons, the results of which have been regularly reported upon in the pages of the *Journal of Agriculture*, the Farm Accounts closed on a Net Profit Balance, aggregating £2,748 18s. 3d. for the seven years. For the first time in the history of the Farm, owing to unfavorable seasonal conditions, the 1928-29 season closed on a Debit Balance; and unfortunately, as will be seen later on, the continuance of unfavorable weather conditions, coupled with the fall in prices of Wheat and Wool, have led to similar results in the 1929-30 season.

#### SCOPE AND DIRECTION OF FARM OPERATIONS.

In the aggregate recorded area of the Farm—1,604 acres—are included 71 acres of quite useless river bed. The net available farming land is therefore represented by 1,533 acres, distributed as follows:—

|                                                  | Acres. | Percentage. |
|--------------------------------------------------|--------|-------------|
| Arable Land . . . . .                            | 1,266  | 82.6        |
| Non-arable grazing land (mostly hilly) . . . . . | 252    | 16.4        |
| Buildings, yards, plantations, &c. . . . .       | 15     | 1.0         |
| Total Available Farming Area . . . . .           | 1,533  | 100.0       |

Within recent years the main lines of exploitation have been Wheat and a Fat Lamb Flock of Sheep, although in the opening years Cereal Hay was the main crop grown. The gradual disappearance of the light horse had, however, rendered the growing of Hay for sale purposes more or less unprofitable, and Turretfield has, in consequence, been thrown back upon Wheat for grain, no more Hay being cut than has been required for home consumption. Towards this end, the Farm has been run on a three-course rotation, as follows:—

- (1) Bare Fallow,
- (2) Wheat, and
- (3) Grazing crops, usually Oats, and Natural pasture.

Portion of the land, however, has been treated on a two-course rotation, namely:—

- (1) Bare Fallow, and (2) Wheat; or
- (1) Pease, and (2) Wheat.

In the 1929-30 season, arable land received the following treatment:—

|                                   | Acres. |
|-----------------------------------|--------|
| 1. Bare Fallow . . . . .          | 471    |
| 2. Fallow Crop (Pease) . . . . .  | 44     |
| 3. Wheat and Cereal Hay . . . . . | 473    |
| 4. Grazing Crops . . . . .        | 177    |
| 5. Natural Pasture . . . . .      | 101    |

Total Arable Land . . . . . 1,266 acres

Originally, the attempt was made to associate a small Dairy Herd and an important Herd of Pigs with normal farm operations. Unfortunately, the inadequacy and costliness of hired labor for the purpose rendered these minor operations unprofitable, and they had to be abandoned. This was unfortunate, because on a farm on which the farmer and his family are mainly responsible for manual operations, these side lines count for much in the financial success of the farm. Should the prices of Wheat and Wool continue at existing low levels, we may possibly be driven back to our original plans.

#### 1929-30 SEASONAL CHARACTERISTICS.

Rainfall recorded at Turretfield in 1929 has been indicated in Table I. in comparison with corresponding figures for preceding 21 years:—

TABLE I.—*Contrasting 1929 Rainfall with Means of Preceding 21 Years.*

|                                          | 1929.          |                 | 1908-28 Means. |                 |
|------------------------------------------|----------------|-----------------|----------------|-----------------|
|                                          | Months.<br>In. | Periods.<br>In. | Months.<br>In. | Periods.<br>In. |
| <b>Late Summer and Autumn Rains—</b>     |                |                 |                |                 |
| January . . . . .                        | 0.34           |                 | 0.57           |                 |
| February . . . . .                       | 0.30           |                 | 0.81           |                 |
| March . . . . .                          | 0.15           |                 | 0.84           |                 |
|                                          |                | 0.79            |                | 2.22            |
| <b>Seeding Rains—</b>                    |                |                 |                |                 |
| April . . . . .                          | 0.60           |                 | 0.73           |                 |
| May . . . . .                            | 0.69           |                 | 2.58           |                 |
|                                          |                | 1.29            |                | 3.31            |
| <b>Winter Rains—</b>                     |                |                 |                |                 |
| June . . . . .                           | 2.13           |                 | 2.25           |                 |
| July . . . . .                           | 1.09           |                 | 2.03           |                 |
|                                          |                | 3.22            |                | 4.28            |
| <b>Spring Rains—</b>                     |                |                 |                |                 |
| August . . . . .                         | 1.61           |                 | 2.05           |                 |
| September . . . . .                      | 1.70           |                 | 2.37           |                 |
| October . . . . .                        | 0.79           |                 | 1.72           |                 |
|                                          |                | 4.10            |                | 6.14            |
| <b>Early Summer Rains—</b>               |                |                 |                |                 |
| November . . . . .                       | 1.42           |                 | 1.05           |                 |
|                                          |                | 1.42            |                | 1.05            |
| <b>Harvest Rains—</b>                    |                |                 |                |                 |
| December . . . . .                       | 2.62           |                 | 0.96           |                 |
|                                          |                | 2.62            |                | 0.96            |
| "Useful" Rain (April-November) . . . . . | 10.03          |                 | 14.78          |                 |
| Yearly Rainfall . . . . .                |                | 13.44           |                | 17.96           |

Table I. shows that in 1929 the total rainfall and its distribution over the growing period of Winter sown crops was even more unfavorable than in the immediately preceding season. The Total Yearly Rainfall—13.44in.—was 4½in., i.e., 25.2 per cent. below normal, and the "Useful" Rainfall—April-November—4½in., i.e., 32.1 per cent. below normal.

The late Summer and Autumn were exceptionally dry—1.43in., or 64.4 per cent. below normal—and succeeding Seeding Rains were altogether inadequate—61.0 per cent. below normal. Indeed, real seeding rain did not reach Turretfield until June. Winter and Spring rains were correspondingly short of requirements—24.8 per cent. and 33.2 per cent. respectively below normal.

November alone was above normal, and, unfortunately, of the 1.42in. recorded for this month, 0.85in., or 60.0 per cent., fell after the 20th of the month, i.e., too late to benefit standing Crops, but in ample time to damage harvest operations, which were further hampered by abnormally heavy December downpours.

Eventually, from 206.09 acres under Wheat we reaped 3,438.8bush., representing a mean yield per acre of 16.69bush. In this total, Wheat following Bare Fallow yielded 17.47bush. and Wheat following Pease 9.17bush. The mean 1921-29 Wheat yield at Turretfield has been represented by 18.83bush.

#### THE 1929-30 BALANCE-SHEET.

The 1929-30 Balance-sheet, copy of which accompanies this Statement, closed on a Debit Balance of £757 5s. This is attributable to two main causes, namely (a) the unfavorable character of the season, and (b) fall in prices of Wheat and Wool.

Credit Balances of the first seven seasons are shown below. Deduction therefrom of Debit Balances of the 1928-29 and 1929-30 seasons leaves accumulated Net Profits aggregating £1,461 1s.:—

|                                               | £      | s. | d. |
|-----------------------------------------------|--------|----|----|
| 1921-22 (nine months) . . . . .               | 398    | 11 | 6  |
| 1922-23 . . . . .                             | 483    | 15 | 9  |
| 1923-24 . . . . .                             | 216    | 5  | 11 |
| 1924-25 . . . . .                             | 1,173  | 15 | 10 |
| 1925-26 . . . . .                             | 79     | 5  | 2  |
| 1926-27 . . . . .                             | 101    | 1  | 7  |
| 1927-28 . . . . .                             | 296    | 2  | 6  |
| <hr/>                                         |        |    |    |
| 1921-28 Net Profits . . . . .                 | 2,748  | 18 | 3  |
| Less 1928-29 and 1929-30 Debit Balances . . . | 1,287  | 17 | 3  |
| <hr/>                                         |        |    |    |
| Accumulated 1921-30 Net Profits . . .         | £1,461 | 1  | 0  |

In these statements of Accounts, the accumulated Net Profits are assumed to represent the Turretfield Personal Capital, and losses occurring in any particular season are met from this Capital. The original Fixed and Floating Capital—£17,590 18s. 2d.—is treated as a Government Loan, and corresponding interest is paid yearly into the State Treasury. In 1925-26 this Loan was reduced by £1,000 from normal farm earnings. In addition, between July 1st, 1921, and April 1st, 1930, the sum of £7,612 5s. 7d., representing Interest on Loan and Overdraft, has been paid into the State Treasury. It follows that over a period of 8½ years the Farm has cost the State nothing, whilst the Treasury has benefited to the extent of £8,612 5s. 7d.

#### INTEREST EARNED BY FARM ON CAPITAL ENGAGED.

If, from the standpoint of a farmer working the farm mainly on borrowed money, we look upon the funds engaged in the farm as being represented by the State original advances—£17,590 18s. 2d.—plus accumulated Net Profits, and less part repayment of Loan, then the rate of interest earned by the farm in each successive year has been shown in Table II.

TABLE II.—*Showing Interest per Annum Earned by Capital Engaged in Turretfield Demonstration Farm, 1921-30.*

|                           | Capital Engaged in Farm. |    |    |           |    |    | Farm Net Earnings.* |    |    |           |    |       | Interest<br>per Annum.<br>Earned.<br>% |
|---------------------------|--------------------------|----|----|-----------|----|----|---------------------|----|----|-----------|----|-------|----------------------------------------|
|                           | Total.                   |    |    | Per Acre. |    |    | Total.              |    |    | Per Acre. |    |       |                                        |
|                           | £                        | s. | d. | £         | s. | d. | £                   | s. | d. | s.        | d. |       |                                        |
| 1921-22 .....             | 17,590                   | 18 | 2  | 11        | 9  | 6  | 1,019               | 12 | 7  | 17        | 9  | 7.73  |                                        |

| 1927-28 .....             | 19,043                   | 13 | 11 | 12        | 8  | 5  | 1,118               | 3  | 4  | 14        | 7  | 5.87  |                                        |
| 1928-29 .....             | 19,339                   | 16 | 5  | 12        | 12 | 4  | 237                 | 16 | 9  | 3         | 1  | 1.23  |                                        |
| 1929-30 .....             | 18,809                   | 4  | 2  | 12        | 5  | 5  | 8                   | 13 | 7  | 0         | 2  | 0.05  |                                        |
| Means of 8½ Seasons ..... | 18,637                   | 19 | 10 | 12        | 3  | 2  | 983                 | 10 | 10 | 12        | 10 | 5.28  |                                        |

It will be observed that interest earned by the Farm on funds successively engaged over 8½ seasons has been represented by 5.28 per cent. This relatively low rate of interest is attributable chiefly to the unfavorable character of the past two seasons, coupled with falling prices for both Wheat and Wool.

The Mean Net Earnings of the farm—£983 10s. 10d.—which represent gross revenue, less costs apart from the equivalent of rental value plus interest on Capital, do not convey much to a farmer, who, together with his family, is usually mainly responsible for farm manual operations. In order to make the position clear it should be stated that in "costs" has been included a mean sum of £1,196 3s. 6d., representing cost of Management and Labor. If we add this sum to farm net earnings indicated above, we get £2,179 14s. 4d., representing the combined Net Earnings of the farmer, his family, and the Capital invested in the enterprise. Finally, if from these net earnings we deduct mean interest dues—£952 7s. 11d.—we would get £1,227 6s. 5d., which would represent the mean Labor Income of a farmer and family exclusively responsible for farm manual operations.

#### PROFIT AND LOSS ACCOUNT.

It has already been stated that the 1929-30 Season closed on a Debit Balance of £757 5s. Details concerning the Profit and Loss Account are shown below:—

#### Profit and Loss Account, 1929-30.

| DR.                       | £      | s. | d. | CR.                        | £      | s. | d. |
|---------------------------|--------|----|----|----------------------------|--------|----|----|
| To Sheep Account .. . . . | 764    | 7  | 8  | By- Farm Stores Account .. | 186    | 3  | 2  |

| Pease Account .. . . .    | 93     | 13 | 10 | Net Loss .. . . .          | 757    | 5  | 0  |
|                           |        |    |    |                            |        |    |    |
|                           | £1,061 | 2  | 11 |                            | £1,061 | 2  | 11 |

As has already been stated, 1929-30 losses are to be attributed chiefly to unfavorable seasonal conditions, coupled with falling prices in Wheat and Wool, and to this must be added decline in price of Sheep. The major loss was on our Fat Lamb Flock which, owing to weather conditions, had to be hand-fed over a great portion of the year. The Profit on Farm Stores was made mainly on the sale of last season's Wheat, which had been valued at 4s. 2d. on March 31st, but sold subsequently at 4s. 8½d., and on the sale of Hay, which had also risen in value.

\* Farm Net Earnings are taken here to represent gross farm revenue, less costs, but exclusive of rental value of land and interest on Capital.

## INTEREST ACCOUNT.

In the statements appearing in the second portion of this Report, interest charged against the various Real Accounts, from which inclusive costs of farming operations are determined, comes from two sources, namely:—

- (1) Interest on original Loan, less repayments, coupled with interest on overdraft, and
- (2) Interest on accumulated Net Profits, representing Turretfield Personal Capital.

The position of the Interest Account for the nine seasons under consideration is shown below in Table III.:—

TABLE III.—*Showing Interest Paid or Debited in Each Year (1921-30).*

| Percentage of capital assets,<br>plus additions, less sales | %<br>20.9    |           |          | %<br>47.1    |           |          | %<br>27.7         |           |           | %<br>57.0           |           |          | %<br>39.1    |           |          |

Hence, between July 1st, 1921, and March 31st, 1930, the original capital value of Buildings, Fences, Water Service, and Tools and Plant—£4,182 10s.—has on the one hand been increased by additions to £6,832 6s. 6d., and on the other reduced by sales or transfers to £6,700 2s. 6d. Again, over the same period, these Capital items have been written down to the extent of £2,617 13s. 5d., or 39.1 per cent. of the original assets, plus additions, less sales. Finally, 1930 valuation has reduced the value of total Capital Assets to £4,082 9s. 1d.

## FARM STORES ACCOUNT.

In these statements, Farm Stores Account has been used as a convenience account to which all farm produce not immediately sold or used has been transferred pending sales or consumption. Produce transferred in this fashion has usually been charged up at current local rates, and it follows that profits or losses are incurred on individual items, at the time of sale or consumption, in proportion to market rises or falls.

The 1929-30 Stores Account closed on a Profit Balance of £186 3s. 2d., the respective Balances of preceding seasons are shown below:—

|                               | £    | s. | d. |
|-------------------------------|------|----|----|
| 1922-23 Profit of . . . . .   | 173  | 19 | 3  |
| 1923-24 Profit of . . . . .   | 74   | 11 | 3  |
| 1924-25 Loss of . . . . .     | 92   | 7  | 9  |
| 1925-26 Profit of . . . . .   | 364  | 10 | 1  |
| 1926-27 Loss of . . . . .     | 132  | 18 | 5  |
| 1927-28 Profit of . . . . .   | 394  | 18 | 4  |
| 1928-29 Loss of . . . . .     | 95   | 13 | 7  |
| 1929-30 Profit of . . . . .   | 186  | 3  | 2  |
| 1922-30 Mean Profit . . . . . | £109 | 2  | 10 |

The fact that over a period of eight years the Farm Stores Account has shown a mean yearly Profit of £109 2s. 10d. serves to show that Farm Produce has usually been transferred to this Account on a sufficiently conservative basis. The 1929-30 Profit Balance was attributable to accidental rises in Farm Produce as follows:—

|                               | £    | s. | d. |
|-------------------------------|------|----|----|
| Hay Sales . . . . .           | 105  | 11 | 5  |
| Wheat Sales . . . . .         | 77   | 0  | 8  |
| Oat Sales . . . . .           | 0    | 2  | 5  |
| Sundries . . . . .            | 3    | 8  | 8  |
| Total Stores Profit . . . . . | £186 | 3  | 2  |

# GRUBBING

## IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY,

## HOUSE-KEEPING ACCOUNT.

The Farm has been responsible for the Board of the Manager, his family, and portion of the Farm Staff. In Table V. below, 1929-30 expenditure in this connection has been summarised in comparison with the means of preceding years:—

TABLE V.—*Summarising 1929-30 House-keeping Expenditure in Comparison with the Means of Preceding Years.*

|                               | 1929-30.<br>£ s. d. | 1922-29<br>Means.<br>£ s. d. | 1922-30 Means.    |                        |

| Provisions .....              | 94 11 2             | 106 12 1                     | 105 2 0           | 33.0                   |
| Farm produce .....            | 52 18 5             | 66 19 1                      | 65 3 11           | 20.5                   |
| Water .....                   | 2 14 6              | 3 12 10                      | 3 10 7            | 1.1                    |
| Kerosene .....                | 4 5 3               | 5 9 8                        | 5 6 8             | 1.7                    |
| Firewood .....                | 6 15 5              | 7 19 5                       | 7 16 5            | 2.5                    |
| Depreciation .....            | 39 4 9              | 47 16 3                      | 46 14 10          | 14.7                   |
| Totals .....                  | 289 17 6            | 322 3 10                     | 318 3 1           | 100.0                  |
| Mean number catered for ..... | 4.62                | 5.57                         | 5.45              |                        |
| Cost per Individual—          |                     |                              |                   |                        |
| Per day .....                 | 0 3 5               | 0 3 2                        | 0 3 2             |                        |
| Per week .....                | 1 4 1               | 1 2 2                        | 1 2 4             |                        |
| Per annum .....               | 62 15 10            | 57 15 3                      | 58 5 9            |                        |

Hence, over a period of eight years, mean inclusive costs of the Boarding House have been at the rates per individual of 3s. 2d. per day, or 22s. 4d. per week, or £58 5s. 9d. per annum.

## WAGES ACCOUNT.

Sums disbursed for Wages in 1929-30 aggregated £1,196 3s. 6d. I have shown below in Table VI. how these sums were distributed in comparison with means of preceding seasons:—

TABLE VI.—*Showing 1929-30 Distribution of Wages in Comparison with Preceding Means.*

|                                     | 1929-30.<br>£ s. d. | 1922-29<br>Means.<br>£ s. d. | 1922-30<br>Means.<br>£ s. d. | Per-<br>centage.<br>% |

## PART II.

## DETAILED ANALYSIS OF FARMING COSTS.

## CAPITAL ACCOUNT.

It is obviously of importance to know what Capital outlay is involved in farming operations carried out on a farm of the Turretfield type. I propose therefore examining this question in detail in the light of operations extending over nine successive seasons.

It should be observed at the outset that at Turretfield the value of the Capital engaged has been successively represented by (1) original—1921—Government advances, covering value of Land, Improvements, Original Stock and Plant, &c., less such repayments as may have been made towards reduction of these advances, and (2) the value of purchases made since 1921, together with accumulated Net Profits, representing Turretfield Personal Capital.

Detailed analysis of the Capital Account on the 1st July, 1921 (original) and the 1st April, 1929, is shown below in Table VIII., together with corresponding mean figures for 1921-28 and 1921-29 periods respectively:—

TABLE VIII.—*Detailed Analysis of Capital Account, 1921-29.*

|                                   | Original Capital, 1/7/21. |    |    | Capital, 1/4/29. |    |    | Mean Capital, 1921-28. |    |    | Mean 1921-29 Capital. |    |    |           |    |    |
|-----------------------------------|---------------------------|----|----|------------------|----|----|------------------------|----|----|-----------------------|----|----|-----------|----|----|
|                                   |                           |    |    |                  |    |    |                        |    |    | Total.                |    |    | Per Acre. |    |    |
|                                   | £                         | s. | d. | £                | s. | d. | £                      | s. | d. | £                     | s. | d. | £         | s. | d. |

| Total Net Capital .....           | £17,590                   | 18 | 2  | £18,809          | 4  | 2  | £18,616                | 11 | 10 | £18,637               | 19 | 10 | £12       | 3  | 2  |

The various items included in the Mean Net Capital per acre—1921-29—admit of being grouped together under the following headings:—

|                                    | Value per Acre. |    |    | Percentage. |
|------------------------------------|-----------------|----|----|-------------|
|                                    | £               | s. | d. | %           |
| Land and improvements .. . . .     | 9               | 4  | 0  | 75.7        |
| Tools and Plant .. . . .           | 0               | 15 | 9  | 6.4         |
| Working Horses .. . . .            | 0               | 5  | 7  | 2.3         |
| Revenue Earning Livestock .. . . . | 0               | 15 | 6  | 6.4         |
| Farm Fallows .. . . .              | 0               | 6  | 7  | 2.7         |
| Sundries .. . . .                  | 0               | 15 | 9  | 6.5         |

Total Mean Net Capital .. . £12 3 2 100.0

It has already been shown that over a period of nine years the mean Net Earnings of the Farm have been at the rate of 12s. 10d. per acre, representing 5.28 per cent. of the mean Net Capital engaged. It follows therefore that on a Farm of this type,

\* "Cash Balance" stands for differences between debtors on the one hand, and creditors and overdraft balance, on the other.

\*\* Eleven shillings and seven pence per acre of produce on hand, or 4.8 per cent. of net capital does not correspond to the mean total of £1,947 18s. From the latter figure have been deducted £948 and £111 2s. 3d., representing respectively mean debtor cash balance and mean annual repayment of principal. This is legitimate since "Produce on hand" must necessarily vary within wide limits, according as available produce is sold before the 31st March in each year, or is reserved for future sale or use, and obviously when so reserved overdraft debtor balance is proportionately increased.

including 17 per cent. to 18 per cent. of non-arable grazing land, it is possible to realise reasonable profits from Wheat and Sheep, even after payment for Management and Labor at standard rates, and with Land and Improvements at £9 per acre and Farming Stock and Plant at £3.

Quite recently I have had occasion to analyse Capital invested in 129 Wheat Farms scattered all over the State\*; it will be of interest to compare the data collected with corresponding figures at Turretfield. In the summarised statement of Table IX., items representing "Farm Fallows" and "Sundries" have been omitted, because the value of "Farm Fallows" is always difficult to estimate on an average Farm and "Sundries" include chiefly unsold Produce, an exceedingly variable item from season to season.

TABLE IX.—*Comparing Capital Items at Turretfield with Corresponding Mean Values of 129 Typical South Australian Wheat Farms.*

| Revenue-earning<br>Livestock ..... | 1,190               | 0 15 6              | 7.0            | 573                 | 0 7 11              | 5.1            |
| Total Capital ....                 | 16,922              | 11 0 10             | 100.0          | 11,207              | 7 16 4              | 100.0          |

From the above it will be seen that in the matter of Total area, and particularly in the matter of available arable area, Turretfield figures approach very closely the means of the 129 Farms examined. On the other hand, Turretfield is relatively a better improved Farm; 63.7 per cent. of its area is cultivated against a corresponding 45.7 per cent.; 36.3 per cent. is under crop against 29.2 per cent.; and 27.4 per cent. treated as bare fallow against 16.5 per cent. Similarly, permanent improvements at Turretfield are represented by £2 2s. 5d. per acre as against £1 13s. 7d., and revenue earning Livestock by 15s. 6d. per acre as against 7s. 11d. Finally, value of Farm Plant is almost identical in either case, namely, 21s. 4d. and 21s. 6d. per acre respectively.

In Table IX. the mean farm under consideration is assumed to represent freehold property having a value of £4 13s. 4d. per acre and involving £7 16s. 4d. of Capital investment. On the other hand, much of the recently settled land in South Australia is held as Crown Leases, under a covenant to purchase, which form of tenure involves the initial immobilisation of far less Capital. If, for instance, we assume our 1,433-acre farm to have been acquired originally at 15s. an acre, as an uncleared Mallee block, under a covenant to purchase agreement, yearly repayments of Principal and Interest would be represented by 60 half-yearly instalments of £2 16s. 5d. per £100 value. We may assume the land to have been completely cleared of scrub in the course of 10 years at the rate of £2 per acre. At the beginning of the eleventh year, Capital value invested in the land by the settler would have become £245 14s. 4d., representing instalment payments of Principal, plus £2,866 representing costs of clearing, or a total of £3,111 14s. 4d. On a per acre basis the settler's interest in the land would therefore be £2 3s. 5d., and assuming the value of other Capital items to remain the same, his

\* See *Journal of Agriculture*, April, 1930, page 772—"An Inquiry into present-day value of Capital invested in South Australian Wheat Farming, and its influence on current costs of production."

total Capital commitments in the eleventh year of occupancy of the block would be represented by £5 6s. 5d. per acre instead of £7 16s. 4d. of the freehold block, and interest charges to be debited against farming operations would be correspondingly lower.

#### INCLUSIVE YEARLY COSTS INVOLVED IN FARMING OPERATIONS.

Apart from the question of the original Capital essential to the acquirement and equipment of a farm, it is perhaps of equal importance to know the extent to which a farmer is likely to be involved in cash expenditure, or corresponding credit, in the yearly working of his farm. Towards this end I have summarised in Table X. mean inclusive costs per annum incurred at Turretfield during eight successive seasons:—

TABLE X.—*Summarising Turretfield Mean Yearly Inclusive Farming Costs (1922-30).*

| Mean Yearly Gross Farm Output . . . . .              | 4,341  | 0  | 9  | 2         | 16 | 7.6  |           |

Attention may be drawn to the following points in Table X.:—

1. Over eight consecutive seasons, inclusive farming costs at Turretfield have been at the mean rate of £4,261 17s. 4d. per annum, or 55s. 7d. per acre.
2. This mean expenditure has over the same period been balanced by a mean Farm Output of £4,341 0s. 9d. per annum, leaving a mean Net Profit of £79 3s. 5d.
3. Out of this mean inclusive expenditure of £4,261 17s. 4d., a sum of £3,208 0s. 2d., or 41s. 10d. per acre, had to be met by actual cash disbursements, whereas £1,053 17s. 2d. or 13s. 9d. per acre, represented book entries and transfers.

4. In this statement, Management and Labor have been assessed at £962 7s. 10d. To this sum should, however, be added £233 15s. 8d. representing value of provisions consumed by employees and of rent for cottages occupied by them, all of which forms integral part of costs of wages. Hence, the aggregate inclusive cost of Management and Wages has been £1,196 3s. 6d., or 15s. 7d. per acre, or again 28.1 per cent. of Total yearly expenditure. If now to the Mean Cost of Management and Wages—£1,196 3s. 6d.—we add the Mean Net Profit—£79 3s. 5d.—we shall get £1,275 6s. 11d., which would represent the Labor Income of a farmer and family mainly responsible for manual operations; corresponding per acre and per cent. figures would be 16s. 8d. and 29.9 per cent.

5. These Mean Inclusive yearly farming costs admit of being grouped together as follows:—

|                                                              | Costs     |       | Percentage. |
|--------------------------------------------------------------|-----------|-------|-------------|
|                                                              | Per Acre. |       |             |
|                                                              | s. d.     | %     |             |
| 1. Management and Labor (including provisions) . . . . .     | 15 7      | 28.1  |             |
| 2. Buildings and Improvements (exclusive of Labor) . . . . . | 0 7       | 1.0   |             |
| 3. Upkeep of Plant (including Horses) . . . . .              | 3 2       | 5.6   |             |
| 4. Purchase of Sheep and other Livestock . . . . .           | 5 1       | 9.1   |             |
| 5. Livestock Foodstuffs . . . . .                            | 9 1       | 16.4  |             |
| 6. Manures . . . . .                                         | 2 2       | 4.0   |             |
| 7. Seed . . . . .                                            | 3 9       | 6.7   |             |
| 8. Sundries . . . . .                                        | 3 0       | 5.4   |             |
| 9. Rates and Taxes . . . . .                                 | 0 8       | 1.2   |             |
| 10. Interest on Capital and Overdraft . . . . .              | 3 3       | 5.8   |             |
| 11. Interest on Land Value (rent) . . . . .                  | 9 3       | 16.7  |             |
| Yearly Inclusive Farming Costs . . . . .                     | 55 7      | 100.0 |             |
| Costs involving Cash payments . . . . .                      | 41 10     | —     |             |

#### MEAN GROSS OUTPUT OF FARM.

It is obvious that if a farm upon which Management and Labor are paid for in hard cash is to continue solvent a mean gross output of a value slightly in excess of mean expenditure figures must be secured. This mean gross output for Turretfield has been summarised in Table XI. for a period of eight successive seasons:—

TABLE XI.—*Summarising Value of Turretfield Mean Gross Output per Annum (1922-30).*

|                                                     | Sold or<br>Used. |       | Differences<br>of Opening<br>and Closing<br>Inventories. |       | Mean Gross Output. |              |                  |  |
|-----------------------------------------------------|------------------|-------|----------------------------------------------------------|-------|--------------------|--------------|------------------|--|
|                                                     |                  |       |                                                          |       | Total.             | Per<br>Acre. | Per-<br>centage. |  |
|                                                     | £                | s. d. | £                                                        | s. d. | £ s. d.            | s.           | —                |  |
| 1. Crops—                                           |                  |       |                                                          |       |                    |              |                  |  |
| Wheat . . . . .                                     | 1,537            | 4 10  | +41                                                      | 4 11  | 1,578 9 9          | 20/7         | 36.4             |  |
| Coroal Hay . . . . .                                | 824              | 17 3  | —38                                                      | 5 8   | 786 11 7           | 10/3         | 18.1             |  |
| Barley . . . . .                                    | 193              | 2 9   | —12                                                      | 6 1   | 180 16 8           | 2/4          | 4.2              |  |

| Poultry . . . . .                                   | 22               | 14 0  | —0                                                       | 7 6   | 22 6 6             | —/4          | 0.5              |  |
| Totals . . . . .                                    | 1,546            | 5 0   | —3                                                       | 8 0   | 1,542 17 0         | 20/2         | 35.5             |  |
| 3. Miscellaneous—                                   |                  |       |                                                          |       |                    |              |                  |  |
|                                                     | 135              | 2 11  | —16                                                      | 11 11 | 118 11 0           | 1/7          | 2.8              |  |
| Mean Total Farm Gross<br>Output per Annum . . . . . | £4,376           | 12 11 | —35                                                      | 12 2  | 4,341 0 9          | 56/8         | 100.0            |  |

It will be observed that over a period of eight successive seasons, the mean yearly value of Gross Farm Output from 1,533 acres of land, 17 per cent. to 18 per cent. of which was non-arable, has been represented by £4,341 0s. 9d., or 56s. 8d. per acre on the total area. Towards this harvested Crops have contributed £2,679 12s. 9d., or 34s. 11d. per acre, or again 61.7 per cent. of the total output; Livestock £1,542 17s., or 20s. 2d. per acre, or again 35.5 per cent. of total output; and Miscellaneous £118 11s., or 1s. 7d. per acre, or again 2.8 per cent. of total output.

MEAN RETURNS AT TURRETFIELD FROM AREAS CROPPED OR GRAZED RESPECTIVELY,  
1922-30.

From data summarised in Table XI. it is possible to determine fairly accurately the mean value of the yearly output secured during eight successive seasons from mean areas concerned with harvested crops only, on the one hand, and from those concerned with grazing Livestock (chiefly Sheep), only, on the other. Such information is of value in any attempt to assess the relative income-earning importance of Crops or Livestock on a mixed farm of the Turretfield type.

During these eight years the mean area under Harvested Crops has been 556 acres, and the mean area treated as Bare Fallow 420 acres; hence, the mean aggregate area allotted yearly to Harvested Crops has been 976 acres. It must be recognised, however, that these 976 acres have not been actively concerned with crops for more than nine months in any one year, and that over the balance of each year they have been available for grazing purposes. It follows therefore that on a per annum basis, these 976 acres are in actual experience equivalent to no more than 732 acres exclusively devoted to harvested crops, leaving the equivalent of 244 acres per annum available for grazing purposes. From this viewpoint a mean output of £2,679 12s. 9d. from harvested crops is equivalent to a return of £3 13s. 3d. per acre from land exclusively devoted to harvested crops.

On the other hand, the mean yearly area available for grazing purposes on the farm may be said to have consisted of the following fractions:—

- (1) 244 acres being the grazing yearly equivalent of 976 acres under crop or bare fallow for nine months in each year, but open to grazing over the remaining three months;
- (2) 290 acres of arable land temporarily out of cultivation or sown to grazing crops; and
- (3) 252 acres of non-arable grazing land.

Hence, over eight successive seasons the mean area open to grazing by farm Livestock has been equivalent in the aggregate to 786 acres.

The mean Value of Gross Output from Livestock has been shown in Table XI. to have been £1,542 17s. per annum; but since over this period foodstuffs have been fed from time to time to normally grazing Livestock, the figure given in Table XI. cannot be looked upon as being derived exclusively from the area open to grazing. From this figure must be deducted the mean value of farm produce fed to Revenue Earning grazing Livestock, namely, £228 19s. 10d. on the one hand, and of purchased foodstuffs used for the same purpose, namely, £33 3s. 3d. on the other. These deductions would have the effect of reducing Mean Gross Output from the exclusively grazed area to £1,280 13s. 11d. On the other hand, however, the latter figure should be increased by £48 4s. 11d., representing the mean value of agistment for Working Horses having access to the grazing area. Hence, the Net value of the Mean Output from that portion of the Farm exclusively grazed has been represented by £1,328 18s. 10d., or £1 13s. 10d. per acre per annum, as against £2,679 12s. 9d., or £3 13s. 3d. per acre per annum from the area exclusively devoted to crops.

The Mean Net Profit from the mean area devoted to Crops on the one hand and to grazing on the other may be determined approximately as follows:—

|                                      | Area Devoted to<br>Crops. |   |       | Area Devoted to<br>Grazing. |   |       |
|--------------------------------------|---------------------------|---|-------|-----------------------------|---|-------|
|                                      | s.                        | £ | s. d. | s.                          | £ | s. d. |
| Mean output per acre .....           | —                         |   |       | —                           |   |       |
| Mean Expenditure per Acre—           |                           | 3 | 13 3  |                             | 1 | 13 10 |
| 1. Interest on land (rent) .....     | 10/5·5                    | — |       | 8/4·4                       | — |       |
| 2. Interest on Working Capital ..... | 4/8·5                     | — |       | 1/10·9                      | — |       |
| 3. Rates and taxes .....             | —/9·5                     | — |       | —7·6                        | — |       |
| 4. Labor .....                       | 22/3                      | — |       | 9/8·6                       | — |       |
| 5. Other expenditure .....           | 34/0·5                    | 3 | 12 3  | 14/4·5                      | 1 | 15 0  |
| Mean Net Profit per acre .....       | —                         | 0 | 1 0   | —                           | — | —     |
| Mean Net Loss per acre .....         | —                         | — | —     | —                           | 0 | 1 2   |

These figures, which show a small profit on Crops and a loss on Grazing, reflect the results of successive bad seasons and gradually falling prices for farm produce on a farm on which Management and Labor are paid for in Cash.

#### INITIAL CAPITAL REQUISITE TO THE SUCCESSFUL WORKING OF A 1,000-ACRE FARM OF THE TURRETFIELD TYPE.

It will probably be recognised in this connection that apart from the position of the average man working in an average season, the minimum initial Capital requisite to the successful working of a Farm would be dependent upon three chief factors, namely:—

- (1) Individual capacity.
- (2) Seasonal conditions over opening years; and
- (3) Current market prices over the same years.

In other words, if an individual farmer have high technical capacity, coupled with good business acumen, if in the opening years of operation he should have the advantage of seasonal conditions and market prices above normal means, it is highly probable that this exceptionally favored individual would be in a position to start farming on a minimum Capital which would lead to disaster the average man facing average or unfavorable conditions. In the development of new country it is, however, inevitable that such implied risks should have frequently been taken. And unfortunately in such circumstances failures have usually outnumbered successes. But, in this connection, it is not my intention to try and determine what should be the minimum Capital upon which the exceptional man could afford to start farming when faced with favorable conditions, but rather to show from the recorded data of eight successive seasons what personal Capital would have been essential to an average man facing similar conditions in order to work successfully a 1,000-acre farm of the Turretfield type.

We must assume a farm of this character to be situated on the heavier land of Central or Lower North Statistical Divisions and to consist of from 820 to 830 acres of arable land, including 9 to 10 acres under buildings, yards, plantations, &c., and 170 to 180 acres of rough grazing land. It may be assumed that a farmer seeking to acquire and work such a farm on a minimum of initial Personal Capital would be able to secure mortgage and loan facilities to the extent of two-thirds of the value of his Capital assets. Reference to Table VII. shows that the Capital requisite to the purchase and equipment of a farm of this type would be represented by £12 3s. 2d. per acre, or for a 1,000-acre farm, approximately £12,000. In the circumstances, the minimum Personal Capital essential to the purpose would be in the neighborhood of £4,000, whilst £8,000 would represent the extent of Loan liabilities, involving at 7 per cent. interest charges of £560 per annum, or 11s. 2d. per acre.

I shall now endeavor to show on the basis of results of eight seasons at Turretfield—1922-30—the extent to which anticipated Revenue and Expenditure would justify farming operations with an initial Personal Capital equivalent to one-third of the value of Capital engaged in the farm.

Reference to Table X. shows that mean yearly expenditure at Turretfield involving direct cash payments has been at the rate of 41s. 10d. per acre. In this figure, however, are included 12s. 7d. paid out in wages, to which should be added 3s. for provisions consumed and 11s. 4d. for interest charges per acre. On the farm that we have in view interest charges have been assumed to be at the rate of 11s. 2d. per acre, and if, as is usually the case, the farm were worked almost exclusively by the farmer and his family, cash payments for wages would to all intents and purposes disappear. In lieu of the latter, however, an adequate sum for the upkeep of the farmer and his family would have to be provided, and towards that end I suggest £300 per annum, or 6s. per acre. Hence, in lieu of the Turretfield figure of 26s. 11d. per acre towards payment of interest and wages, a sum of 17s. 2d. per acre should suffice on a farm worked mainly by a farmer and his family. It follows, therefore, that in such circumstances total Cash outgoings per annum need not exceed 32s. 1d. per acre, or £1,604 on a 1,000-acre farm.

Again, reference to Table XI. shows that at Turretfield the mean value of Farm output per annum has been at the rate of £4,341 0s. 9d., or 56s. 8d. per acre. Of the latter sum, not less than £3,323 have represented direct Cash receipts. Hence, in the circumstances already indicated, a farmer working a 1,000-acre farm of the same type could anticipate a mean farm output of £2,832, of which not less than £2,168 would represent direct Cash receipts. Output on this scale would be more than adequate to meet estimated mean Cash outgoings of £1,604, and would leave ample margin for unforeseen emergencies and occasional payment of casual hired labor.

I conclude, therefore, that in competent hands a Personal Capital of £4,000 should suffice for the purchase, equipment, and working of a 1,000-acre Farm of the Turretfield type.

#### GENERAL EXPENSES ACCOUNT.

In any business occupation, and to a greater extent in farming than in any other, numerous items of expenditure are incurred in the course of a year's operations which cannot readily be debited against any particular Real Account. In the aggregate, these items of expenditure represent the overhead charges which must eventually be distributed among Revenue Earning Accounts, and usually in proportion to the relative monetary importance of each.

In Table XII. below have been summarised mean General Expenses incurred at Turretfield over eight consecutive seasons:—

TABLE XII.—*Summarising Mean General Expenses per Annum Incurred at Turretfield (1922-30).*

|                                                 | 1922-30 Mean General Expenses per Annum. |           |           |  |
|-------------------------------------------------|------------------------------------------|-----------|-----------|--|
|                                                 | Total.                                   | Per Acre. | Per cent. |  |
|                                                 | £ s. d.                                  | s.        | %         |  |
| 1. Interest on Floating Capital and Overdraft . | 247 8 7                                  | 3/3       | 35·8      |  |
| 2. Wages .....                                  | 240 7 8                                  | 3/2       | 34·8      |  |
| 3. Depreciation .....                           | 78 12 8                                  | 1/-       | 11·4      |  |
| 4. Rates and taxes .....                        | 53 12 10                                 | -/8       | 7·7       |  |
| 5. Sundries .....                               | 44 16 11                                 | -/7       | 6·5       |  |
| 6. Use of implements .....                      | 15 0 6                                   | -/2       | 2·2       |  |
| 7. Use of horses .....                          | 11 7 10                                  | -/2       | 1·6       |  |
| Totals.....                                     | 691 7 0                                  | 9/-       | 100·0     |  |
| Mean Yearly Total Expenditure .....             | 4,261 17 4                               | 55/7      | —         |  |
| Percentage of Total Expenditure .....           | —                                        | —         | 16·22     |  |

Thus, then, over a period of eight years "General Expenses" at Turretfield have been represented by a mean value of £691 7s. per annum, or 9s. per acre, or again 16.22 per cent. of a Mean Total Expenditure incurred.

[To be continued.]

## THE IMPORTANCE OF CROSS-BRED WHEATS TO SOUTH AUSTRALIA.

[Summary of an address delivered to the Rotary Club by W. J. Spafford,  
Deputy Director of Agriculture.]

The Wheat crop is of the greatest importance to this State, as can be seen by a glance at the following Table:—

### *Value of Production—Means, 1924-1928.*

|                          |             |
|--------------------------|-------------|
| Total value .....        | £39,263,747 |
| <i>Agricultural—</i>     |             |
| Wheat .....              | £9,340,493  |
| Sheep .....              | 6,312,665   |
| Vines .....              | 1,996,680   |
| Other livestock .....    | 3,540,083   |
| Other crops .....        | 3,364,817   |
|                          | £24,554,738 |
| <i>Non-Agricultural—</i> |             |
| Manufactures .....       | 12,393,445  |
| Mining .....             | 1,447,107   |
| Miscellaneous .....      | 1,268,457   |
|                          | £14,709,009 |

These figures disclose that of a total value for production of about 39½ million pounds, agriculture provides about 24½ million pounds, and of this the Wheat crop accounts for about 9½ million pounds.

Perhaps the position of the value of our overseas exports is of still more importance in a country with no manufacturing advantages, because from exports we receive new money, and the principal export lines are:—

### *Value of Oversea Exports—Means, 1924-1928.*

|                                   |             |
|-----------------------------------|-------------|
| Total Value of Exports .....      | £17,621,555 |
| <i>Agricultural Exports .....</i> | £13,356,797 |
| Wheat .....                       | £6,525,212  |
| Sheep .....                       | 5,219,960   |
| Vines .....                       | 873,979     |

The value of agricultural overseas exports represents 76 per cent. of the value of total exports, but if we make allowance for the value of the New South Wales' material we export overseas from Port Pirie, the proportion of agricultural exports to total exports becomes 90 per cent. Of these overseas exports Wheat has brought in about 6½ million pounds per annum, and is our principal exportable product.

Last year South Australian farmers grew 212 varieties of Wheat, but most of these were grown on very small areas. As a matter of fact, the nine most important wheats of the State—each of which was grown on over 100,000 acres—covered a total area of about 2½ millions of acres, or 69 per cent. of the total area of about 4,000,000 acres. The 20 most important wheats grown were harvested from about 3½ millions of acres, or 87 per cent. of the total area reaped. By examining a list of the areas sown to various wheats, it shows that:—

- (a) Although farmers grow a lot of varieties of wheat, relatively few kinds are used on the great bulk of the area sown;
- (b) Of the principal wheats of the State, only one—Gluyas—was known 30 years ago;
- (c) All of the most important wheats, except Gluyas, were produced by specialists in plant breeding;

- (d) Of the nine most important wheats grown here, five originated at Roseworthy Agricultural College;
- (e) The area sown to Roseworthy Wheats aggregated about 1½ million of acres last year, and equalled 37 per cent. of the total area sown.

We have made considerable progress in wheat growing in the past 40 years, as shown by the average yield secured per acre for each of the four decades:—

*Progress of Wheat Growing since 1889.*

| Decade.           | Mean area harvested. |  | Mean yield per acre. |    |
|-------------------|----------------------|--|----------------------|----|
|                   | Acres.               |  | Bush. Lbs.           |    |
| 1889-1898 .. .. . | 1,646,976            |  | 4                    | 48 |
| 1899-1908 .. .. . | 1,766,668            |  | 7                    | 40 |
| 1909-1918 .. .. . | 2,310,095            |  | 10                   | 31 |
| 1919-1928 .. .. . | 2,547,090            |  | 11                   | 7  |

Although much of the increased wheat yield is due to improved cultivation practices, the use of superphosphate, &c., still we feel that quite a lot of it can be credited to improvement in the varieties of wheat now being grown. If during the past 20 years, when a lot of the improvement has taken place, we allow that only 1 bush. per acre of the increase is due to the use of Australian-bred wheats, the increase was worth to South Australia, at the actual average price received during the period, 12½ million pounds, or £635,000 per annum. If we allow that half-bushel per acre of the increase was due to the introduction of Roseworthy wheats, the increased value to the farmers of the State would be 6½ million pounds, or £317,500 per annum. There is no way of arriving at the actual increase due to the breeding of new wheats, because improvements are being made all along the line, but if only one-quarter of the increase suggested has resulted from the breeding of the new wheats at Roseworthy College, which were sown on 1½ millions of acres last year, the total expenditure on the institution has been repaid many times.

The cross-fertilization of wheat is a very simple operation. The flowers are hermaphrodite, i.e., possess both female and male organs, and cross-fertilization consists in extracting the male organs from a few flowers on a wheat head, replacing them with pollen sacs from the variety which is to be the male parent, removing all unfertilized flowers from the head, and protecting the remainder so that they will not be interfered with by wind or insects.

Although cross-fertilizing wheats is very easy, it is quite another matter when it comes to "fixing" useful new varieties resulting from the cross-breeding, and considerable difficulty is experienced in this direction. Every wheat variety is a combination of a large number of separate characters, most of which answer to Mendel's Law, and as such are *dominant* or *recessive* to the opposite of that character. When such opposed characters are mated together they do not combine, but remain as separate characters in the offspring, and the *recessive* character is always overshadowed by the *dominant*. For instance, if a beardless wheat is mated to a bearded variety the first generation offspring is always beardless, no matter which kind was used as female parent, beardlessness being *dominant* to beard. In the second generation about one-quarter of the plants are bearded, and will always throw true-to-type, whilst three-quarters are beardless, and one-third of these will always throw true-to-type, whereas the other two-thirds continue to throw the same mixture of three *dominants* to one *recessive*. Where two characters are concerned, such as brown chaff and beardlessness, mated to white chaff and bearded, the possible combinations are considerably increased. Absence of

beard and brown chaff being *dominant* characters, the first generation offspring are all brown and beardless. In the next generation the plants are approximately in the following proportions, of:—

Nine brown-beardless, three brown-bearded, three white-beardless, and one white-bearded.

The complications become greater and greater as the number of characters concerned are increased, and for a single character the possible combinations are four; for two characters the possible combinations are 16; for three characters the possible combinations are 64; for four characters the enormous number of 256 possibilities is reached, and so on, as the opposed characters increase.

The separation of a useful new variety from the very great assortment resulting from a cross of two distinct kinds of wheat is a very difficult matter, as can be realised, and in some cases takes many years to "fix" so that it reproduces itself true-to-type. It is because of the knowledge required, and the difficulty experienced, that it is essential for the work to be done by specialists, and as it is important that the work be continued in a wheat-growing country such as is South Australia, every encouragement should be given to those engaged in the work.

---

## ORCHARD NOTES FOR SOUTHERN DISTRICTS, NOVEMBER, 1930.

---

[By CHAS. H. BEAUMONT, District Horticultural Instructor].

---

This month will probably decide the amount of fruit to be harvested and also its quality. Apricots and peaches should be thinned off if the crop sets too thickly. By doing this there will not be a sacrifice of quantity, and the best quality will be obtained, and therefore a better price. When picking, keep the riper ones away from the firm ones and pack separately; good peaches are worth placing on trays.

Grapegrowers must continue to watch for "Downy Mildew," as vineyards are liable to get it if the season keeps moist; use "Bordeaux Mixture," either wet or dry, so soon as the mildew is noticed and prevent its spread. For "Oidium" use sulphur dust. If young vines are being attacked by "cutworm," dust with arsenate of lead. Codlin moth must be kept in check; so far we have no better remedy than arsenate of lead, but many are trying Volek or Alboleum oils.

Strawberries require considerable attention. Weeds must be kept down; a mulch improves the crop. Paper mulch is easily applied and will last two seasons; it will check the weeds. Packages of strawberries should be even throughout and not be topped up with a layer of large ripe ones and small green ones lower down. Be ready to stop cherry or pear slug; a light dusting with arsenate of lead will stop it. Hawthorn and other shrubs are often attacked by this insect.

Orchard and vineyard soil should be kept lightly stirred to prevent the penetration of heat; especially see to this close to the main stems. Weeds must be kept away from the trees and vines.

Trays and equipment for drying fruit should be put into good order and be thoroughly cleaned, to be ready for use if there is excess fruit; there is no need to waste any fruit which is well grown. Portable dehydrators are now obtainable and are not difficult to erect.

## "TAKE-ALL" AND "NO-GROWTH" DISEASES OF WHEAT AND OTHER CEREALS.

### REQUEST FOR SPECIMENS.

[By S. D. GARRETT, B.A., Waite Agricultural Research Institute.]

During the past winter many specimens of wheat and other cereals affected with the "No-growth" disease have been examined at the Waite Institute. (By the term "No-growth" is understood the stunting and killing of wheat and oats in the early stages of growth; the term "Take-all" as here used refers to the empty ears and dead or dying condition of plants at the heading stage, and in this sense, therefore, is synonymous with the terms "Whiteheads" and "Hay-die," also used to describe this condition.)

Some of the "No-growth" patches have been found to be due to attack by the nematode, or eelworm, *Heterodera schachtii*; from other patches, however, a number of different fungi have been obtained. Of these, two are of major importance—*Rhizoctonia* sp. and "*Brachysporium*."

*Rhizoctonia* sp. was first recorded as causing a "No-growth" disease of wheat and oats in South Australia by Samuel (this journal, vol. XXXII, pp. 40-43) in 1928. It has also been reported as causing a similar disease of cereals from India, Italy, and the United States of America. The fungus has again been isolated this winter from a number of "No-growth" patches in different parts of the State.

Two Petri Dishes containing (left) three colonies of "*Brachysporium*," and one colony of *Helminthosporium Sativum*, and (right) two colonies of *Rhizoctonia*, all growing out from pieces of diseased wheat stems.

Of equal importance appears to be a fungus which has been given the temporary name of "*Brachysporium*" (a culture has been sent away for expert identification); it approximates very closely to the species *Acrothecium lunatum* Wakker, which has been recorded on cereals from India, Ceylon, and the Gold Coast. Unlike *Rhizoctonia* sp., this fungus has been isolated from "Take-all" patches by the Plant Pathologist, Mr. Samuel, in previous years. It has not, however, been isolated from "No-growth" patches previous to this year. The damage caused by this fungus is often considerable, more than half the paddock frequently being thus affected in the early stages of growth, though it is probable that other factors as well as the fungus are contributory to an attack of such severity. A characteristic feature of the "*Brachysporium*" disease

(which has already been remarked for the *Helminthosporium sativum* footrot of wheat by W. M. Carne, *Western Australian Agricultural Journal of Agriculture*, Vol. IV., 1927) is that the affected areas may be of any size and shape, and that, furthermore, single diseased plants may be found scattered right through the crop. The Rhizoetonia disease, on the other hand, is always found in patches approximately circular, and generally of more limited extent. This is doubtless due to the fact that Rhizoetonia spreads from a chance starting point in the soil by outwards growth in all directions simultaneously, as does the Mushroom fungus, whereas "Brachysporium" is widely distributed over the surface of the paddock by means of its wind-borne spores.

A third fungus obtained from "No-growth" patches, but of considerably less frequent occurrence, is *Helminthosporium sativum*, P.K. & B., which is of world-wide distribution, and has been shown in America to attack all cereals and many species of grasses.

Tests are at present being conducted with these fungi, in order to discover, firstly, a resistant variety of wheat, and, secondly, their respective host ranges. Thus, if "Brachysporium" can attack wheat, barley, oats, and rye, as is thought very probable, control of the disease by the rotation of oats or barley with the wheat will obviously be out of the question.

*Farmers are in a position to render very material assistance to these investigations.* It is asked that those who have "Take-all" on their land, especially in paddocks where "No-growth" has been observed earlier in the season in this or previous years, may be kind enough to send specimens of "Take-all" to the Assistant Plant Pathologist, the Waite Institute, Glen Osmond. Where possible, a bundle of not less than 50 plants should be sent, the roots and 6 in. of the straw being all that is required for the isolation of the fungus. Specimens should be accompanied by a statement as to whether "No-growth" has appeared in the same paddock earlier in the year. Those so doing will be informed in due course as to the particular fungus causing the "Take-all" condition in their plants.

## PASTURES AND PASTURE MANAGEMENT.

Mr. L. J. Cook, B.D.A. (Manager Kybybolite Experimental Farm), read the following paper:—

In growing and handling pastures, as in producing a crop of wheat, oats, or barley, one should have an ideal of perfection in one's mind. In breeding animals we always have a model of the most perfect type in our mind, to which we strive to breed a herd or flock, and to do this every attention is necessary to be paid to their fodder. Breeding counts a lot, but feed is equally as important, and best quality feed is necessary to produce best quality stock. Pasture is the most economical feed for livestock, and hence the importance of making pastures the best possible.

## AN IDEAL PASTURE.

The study of pasture is quite different from that of hay or grain crops. With the one, the initial and early growth, and its persistent production is the important object; whereas with the hay or grain crops we aim for perfection in fully matured plants. It has long been known by the practical grazier that the young, early growth of grass is more nutritious and palatable to livestock than the older or more fully developed growths, and during the last decade scientists have spent much on pastures, and have proved theoretically that this short young growth is particularly nutritious. When deprived of the water contained in young grass the dry matter is a highly concentrated food, equal to such foods as linseed meals, cakes, &c. Especially is this so when grass has been produced from rich or well-fertilised soils. Knowing this fact, the first quality for which we look in an ideal pasture is young grass about 1½ in. to 3 in. high.

The second factor is the thickness and evenness of sward. All the land should be occupied by the pasture plants; no bare spaces, or moss-covered patches, but the soil should be covered like a lawn. Patches of rankness inches higher than the rest, where a heap of dung or organic matter has been dropped, or growths of inferior weeds are not required.

Thirdly, the color. An ideal pasture should be a beautiful, healthy, bright-green color, not dull and dark, or a sickly yellow through lack of correct fertilisation, drainage, or management.

Fourthly, the composition of the pasture. Our ideal should contain a mixture of the good feeding types of grasses and clovers, approximately 70 per cent. to 75 per cent. of grasses, and 25 per cent. to 30 per cent. clovers. The numbers and varieties of these must naturally vary according to local conditions of soil and climate and the ability of species to thrive, but the greater the mixture of palatable types the better.

Such a pasture as pictured above is ideal for growing and milk-producing livestock.

In countries with adequate, evenly distributed rainfall, such as England and New Zealand, this ideal of pasture is possible to maintain constantly throughout the bulk of the twelve months of each year. Probably only in our extreme South-East, or where irrigation is available, could such be obtained in South Australia. However, our aim should be, where we make pasture our main crop, to have this ideal available for as long in the year as we possibly can.

On much of our pasture land we can characterise the growth of plants as follows:—A fair growth in late autumn and early winter, according to the quantity and frequency of early rains, whilst the soil is warm. A check in development during the winter months, varying, of course, in districts, but mainly controlled by soil temperatures, which are in turn largely affected by the amount of organic matter present in the soil. Then in the spring of the year comes the flush, a more or less rapid and quick growth of plants towards maturity. During the summer months green growths are limited to our rather unreliable rainfall of that period.

Our aim should be to so treat and manage our pastures to encourage more or less continuous even growth, particularly during the winter months, and endeavor to extend the growing period, so that the young growing grass would be available for as great length of the season as possible. This would not only be advantageous to the sheep grazer, but infinitely valuable to the dairyman, who can by this means supply rich, succulent food to his milkers.

So much for the aims and ideal of pasture. Ways and means of improvement at hand are as follows:—

- (1) Fertilising or manuring.
- (2) Sowing suitable mixtures of seeds.
- (3) Rotation of grazing.
- (4) Harrowing.
- (5) Mowing.

#### FERTILISING PASTURES.

By manuring correctly more can be gained towards ideal pastures probably than by the other methods. All are supplementary one to the other, but except perhaps in the case of extremely rich soils, the sowing and cultivation of suitable seeds, and the correct grazing of pastures, would be comparatively useless without resorting to the use of manures.

We have long since discovered that pasture plants require feeding with artificial manures, just as much as our cereal and other crops. Like them, phosphatic fertiliser is the first and most important required, simply because most of our soils lack this mineral naturally, and because readily available phosphatic fertiliser, such as superphosphate gives such added strength to young plants, and helps them to obtain a strong root-hold in their early life. As regards the form and quantity of phosphatic fertiliser to apply, this is liable to vary in different districts. Generally speaking, the water soluble form superphosphate is the best to use, and gives the quickest return. On certain naturally slightly acid soils, such as we have in the red gum lands of the South-East, citrate and acid soluble phosphates have given very good results, and in wetter seasons have given equal results with superphosphate, at a slightly reduced cost; but, taking the average for the past five seasons, superphosphate has, even on these soils, given the greater yield of pasture. For instance, some Kybybolite results on red gum land, with an annual rainfall of 19½ in., show that an annual dressing of 1 cwt. 45 per cent. superphosphate increased the carrying capacity on sown pasture 135 per cent., whilst a single dressing of 6 cwt. 61 per cent. Ephos phosphate and 4 cwt. 82 per cent. Island phosphate increased similar pasture 122 per cent. and 79 per cent. respectively, and a single combination dressing of Island Phosphate and Super increased 110 per cent. With natural pastures super increased carrying capacity 118 per cent., whilst Ephos Phosphate increased 101 per cent. and calcium rock phosphate increased 115 per cent. In perusing the grazing for the five winters, taking the months May, June, July, and August, we find that the proportion of carrying capacity has been similar in increase. The rainfall for these four months for the five years has, on the average, been 11.3 per cent. below the means for the past 24 seasons, and not in any of these seasons, during the winter period, has the rainfall reached the mean. Had the seasons been wetter, we could have possibly expected a greater response from the less soluble phosphatic fertilisers.

With reference to quantity of phosphatic fertiliser to apply, we have found that annual dressings of superphosphate give the more even results, and so far as tests have gone greatest production of pasture has been secured by the application of 180lbs. 45 per cent. per annum. The results from Wimmera Rye Grass and Subterranean Clover for the past two seasons have been:—

4.86 sheep per acre carrying capacity from 180lbs. 45 per cent., or 312 per cent. increase.

4.21 sheep per acre carrying capacity from 90lbs. 45 per cent., or 257 per cent. increase.

2.64 sheep per acre carrying capacity from 45lbs. 45 per cent., or 124 per cent. increase.

1.18 sheep per acre carrying capacity from no manure (check plot).

Comparing the Winter grazing for the immediate past three seasons on these particular plots we find that 45lbs. 45 per cent. Super has increased the winter grazing 59 per cent., 90lbs. 45 per cent. Super increased 111 per cent., and 180lbs. increased 119 per cent. These results show that with this class of pasture, that at least applications of 90lbs. 45 per cent. super annually would be amply repaid, and with sheep at a reasonable value applications up to 180lbs. would pay.

In the top-dressing of superphosphate on natural pasture we find that the carrying capacity for four annual applications of 90lbs. 45 per cent. to be 1.55 sheep per acre, an increase of 125 per cent. above check plot, whilst four annual applications of 180lbs. 45 per cent. has carried 1.70 sheep per acre, or 146 per cent. increase above no manure, and 21 per cent. increase on the 90lb. application. The heavy application, therefore, has not in this case proved payable.

#### POTASSIC FERTILISER.

Potash is known to have a good effect on the growing tissues of plants, more especially on pasture plots and root developing crops. Consequently, it could be anticipated that potassic fertilisers would have a beneficial improvement on the development of our pastures. Tests of it on Subterranean Clover and Wimmera Rye Grass pasture have been carried out at Kybybolite for five seasons. Only a small annual application of 37lbs. 90 per cent. Sulphate of Potash has been applied. This is equivalent to approximately 18lbs. soluble potash per acre, and costs in Adelaide about 4s. 8d. This dressing when applied without any phosphatic fertiliser has given an increase of 0.58 sheep per acre, or 38.7 per cent. above no manure. The same dressing when applied with rock phosphate has given an increase of 0.45 sheep per acre, or 33.8 per cent. above that receiving only an equal amount of rock phosphate. Hence, from these two results it appears that on this class of pasture an application of potash will give an increase of  $\frac{1}{2}$  sheep per acre at a cost of 4s. 8d. for fertiliser, plus cost of application. From this point of view it is scarcely a payable proposition, but investigation is yet necessary to discover whether potash fertiliser, in addition to phosphatic, will give an improved health to stock or a greater development to carcase, wool, or milk production.

#### NITROGENOUS FERTILISER.

Nitrogen has a good effect on growth development, especially on leaf and stem of grasses. Instance the quick response of lawns to the application of sulphate of ammonia, it can therefore be expected that when applied to pastures, nitrates would help the better grasses to overcome weeds, and particularly to improve growth during winter months, when wet and cold conditions are liable to cause a shortage of nitrates in available proximity to plant roots. The nitrates of the soil are greatly increased by the clovers of pastures, which fix the nitrogen of the air in available plant food form in the soil by the aid of soil bacteria. It is somewhat doubtful, therefore, whether artificial nitrogenous fertilisers applied to old-established clover pastures would show much added benefit. However, little work has as yet been done to test the results of applications of these fertilisers. Tests have been commenced, and indications are that they will give a quick impetus to the growth of grass in pastures, and by being applied

in the late autumn they will increase the amount of winter feed and improve its color and appearance. We have yet to test the economics of applying this comparatively costly fertiliser, but it is possible under an intensive pasture system that dairy farmers will obtain good remuneration from the use of nitrates applied with phosphates.

#### LIME.

Lime is more a soil amendment than a fertiliser, and as such plays a good part in improving the fertility of soils, by making the natural ingredients of soils available for use of plants. There is quite a large area of land in South Australia needing lime before bringing it to full fertility, and those most urgently needing lime are those in which sorrel quickly thrives when land is cultivated. This type of land is suitable for the cultivation of Subterranean Clover and Rye Grass pastures, on which we have been experimenting for the past five or six years. Results so far have shown that the average annual carrying capacity of this pasture dressed with 1 cwt. 45 per cent. Super. per annum is 3.95 sheep per acre, whilst that dressed with Lime as well as equal dressings of super has carried 3.70 sheep per acre. Lime has, therefore, depressed the yield of pasture by  $\frac{1}{4}$  sheep per acre, and in only one out of the five seasons under review has the Lime and Super plot exceeded that of super only. This was the fifth and most recent season; the one furthest removed from the application of lime.

In considering the winter feed, we find that for the four months—May, June, July, and August—the average on the Lime and Super plot has been 3.45 sheep per acre as against 2.93 sheep per acre on the plot which received super only. These figures are a true indication of the effect of lime on this pasture in this type of soil. The limed plots invariably make quicker and better growth throughout the Autumn and Winter months, and cause a better growth of grass and a greater variety of plants to appear in the pasture. There is apparently less clover and a consequent reduction in the quantity of late summer feed.

In considering the effect of lime applied to the natural pastures of this type of soil we find a greater advantage showing for lime against super. For instance, during the same five seasons, 1925-30, Lime and super applied to the natural uncultivated pastures have carried an average of 2.30 sheep per acre as against super only carrying 1.92 sheep per acre. Similar land unimproved has carried 0.88 sheep per acre, hence the increase over no manure has been 1.42 sheep per acre in the case of lime and super and 1.04 sheep in the case of super only. Hence the increase due to lime shows as 0.38 sheep. Comparing the four winter months—May to August—the lime and super plot has carried 2.05 sheep and Super only 1.90 sheep per acre, which again shows an advantage in winter feed provided by the application of lime.

With reference to the quantity of lime, these plots are based on an application of 1 ton per acre every 10 years. One ton per acre will sweeten or neutralise the surface soil of this type, and will maintain it so from 8 to 10 years. The cost of a ton application will, of course, vary with the nearness of the place of supply, but in most districts it should be available at £2 or 45s. per ton. This, plus cost of carting and spreading, should be on the land for £3 at the most.

#### TIME OF APPLYING FERTILISER TO PASTURES.

Topdressing of pastures should be done in the Autumn months so that plants can secure the benefit of fertilisers during their initial growth, and are thereby able to be at their best during the winter months, and have the full benefit during the whole of their growing period. Spring applications will be beneficial when pastures have been extremely hard fed during winter.

In summarising the fertilising of pastures, note that superphosphate gives the greatest return in bulk of feed throughout the whole year, and that applications of 1 cwt. per acre give good payable returns.

Agricultural lime, in addition, gives improved winter growth, and a greater variety of plants, with a better percentage of grass.

Nitrogen and Potash fertilisers both cause increased growth, but at present prices of commodities it is doubtful whether remunerative returns can be gained by their use.

Figures quoted are the results so far secured from work carried out at Kybybolite. We have not yet been able to study the effect of manuring on the growth and development of sheep and wool, or on milk production. Practical experience shows that larger frames, and more wool, and milk are produced, but actual figures are not yet available.

#### SOWING SUITABLE MIXTURES OF SEEDS.

There is a great variation in the types of plants that constitute a pasture, but the main and most important are the grasses and clovers. These in themselves vary immensely. The period of growth is markedly different, some being more prominent in winter, while others show their best during the flush of the season, and others prefer the hotter months of summer. Soil types and conditions have an effect, some plants being particularly amenable or adverse to certain sorts of soils. They vary in palatability, stock preferring certain types more than others, although this factor can be largely altered by correct handling and fertilising.

The aim is to find the types that suit local conditions and encourage the best from them. For instance, where Subterranean Clover and Rye Grass will thrive make them the best possible, or where rich flat land is available encourage better clovers such as Strawberry, White Dutch, Alsike, and Trefoil, with grasses such as Perennial Rye, Cocksfoot, Phalaris, etc.

In considering the seeding of pastures three matters are of importance. First secure good sound seed of high germinating ability from a reliable source. Secondly, remember that clovers are very useful and needed in pastures, but at the same time, all clover and no grass is not the best pasture. An ideal pasture contains only 25 per cent. to 30 per cent. clover, and it is up to the agriculturist to see that the 60 per cent. or 70 per cent. of grass is of good species.

When Subterranean clover is first sown in its good environment, it tends to monopolise the soil, but after a few years will become grassy with naturalised types such as Sterile Brome, Silver, and Barley Grass. The qualities of these, especially in certain stages of their growth, are quite all right, but better are available. Hence, encourage better grasses, particularly good winter growers such as the Rye Grasses and types of Phalaris. The feed of these is superior to that of the naturalised types, and if given a chance will tend to keep the others in check. It is advisable to always sow grass with clover.

Thirdly, when establishing a pasture, give it a good start by preparing the land well. Few farmers would expect to produce first class crops without fallowing and well preparing the land. The same applies to pastures, preparing the soil well or even fallowing often means the difference between success and failure. It is a very convenient method to sow Subterranean Clover and Wimmera Rye Grass with a cover crop, but in many cases better stands are obtained by sowing them as a mixture without the cover crop, and handling them correctly. Where mixtures of finer seeds are sown it is imperative to prepare a really good fine seed bed.

#### ROTATION OF GRAZING.

The grazing of a pasture is all important, and correct management means the carrying of more and healthier stock.

The old idea of sheep in every paddock is not a good practice on improved pastures. Strictly speaking, there should be at least four fields for every flock or herd, so that the pasture is grazed down quickly and evenly, and then left for a period to make further healthy growth. By this means plants are able to strengthen their roots. When stock are running indiscriminately over a large area they pick out the choicer patches and concentrate upon them, and when plants are consistently nibbled off at soil surface their roots are unable to function fully through shortage of ingredients brought

to them through their leaves. Hence pastures should be allowed to grow undisturbed until they are 1½ in. to 2 in. high, and then grazed off comparatively quickly. By adopting a system of rotation with grazing fields, which should be as near as practical of an equal area, farmers could have a more or less continuous supply of young grass available. On pastures in the South-East grazed in this way, 10 to 12 sheep are used to the acre, and pastures thereby are given three weeks spell in every four during the winter months. As the flush of the season approaches certain fields are left for haymaking, and flocks are concentrated on fewer fields with less changes. The size of fields should vary according to the type of stock, and the size of flocks and herds. From 20 to 25 acre fields are a suitable size for sheep flocks of from 200 to 250 head under Kybybolite conditions. Under good dairying conditions even smaller fields will probably be found more advantageous. We read of New Zealand and English dairymen with fields no larger than five or six acres, which they graze with 12 cows to the acre at a time.

#### HARROWING.

The harrowing of permanent pastures that have been heavily stocked is most important, as the spreading of the droppings of livestock evenly over the soil surface leads to greater and more even fertility. Droppings, if not broken and scattered, cause an excess of organic matter on certain portions of pastures, causing rank and unpalatable growths. These growths are the last that stock will eat when grazing on a field, are not of high feed value, and their production should be discouraged.

Good pastures that carry up to half cow or more per acre soon become thickly dotted with manure droppings, and it becomes essential to treat such fields. Harrowing is the best means, and pasture harrows are now available that will do satisfactory work. They are many tined and are short in the tooth. Dragged forward in the Autumn months, they give a good stirring to the pasture surface, and when used, reversed, during the Winter months after grazing, they will fairly readily scatter the fresh droppings without materially affecting the sole of grass. The use of pig netting weighted down also is a good means of spreading manure droppings.

#### MOWING.

The use of the mower is becoming increasingly necessary every season. Its importance is becoming realised when maximum production is desired from our pastures. Growing pastures can be improved, if rank patches are mown off when not consumed by grazing stock. The fresh growth that follows is usually much more palatable, and will be eaten more readily by stock. However, the greater use of the mower is in the making of hay. Under conditions such as our Winter rainfall areas, where we naturally have a heavy flush growth in the Spring followed by a comparatively dry period during summer and early autumn, when green growths are mostly absent from our pastures, some provision is necessary to carry our stock over the dry period. It is not practical to always stock our pastures to the full capacity during the flush season, consequently it pays to shut off certain fields from grazing at this period, and when about at their complete vegetative growth, mow them, and turn the pasture into valuable meadow hay, which can be stored and utilised during the lean periods of the year. These fields when mown and cleared of hay will respond to late spring and early summer rains, and give a green picking to livestock later into the year than could be obtained if no mowing were done.

The alternative method to mowing is to allow the excess spring growths to mature in the fields, and be left for stock to graze in the dry state. Whilst this dry feed has a value which is comparatively good in some cases, such as where a lot of ripened clover seed is available for stock, it is wasteful. Experience shows that livestock prefer good cured meadow hay to this dried up pasture, a lot of whose nourishment has been lost to animals, through valuable ingredients being leached from it by the actions of sun and rain. It contains a high percentage of fibre and indigestible matter

which is not readily assimilated. Hence, though it is a food that will maintain stock, and possibly fatten grown animals, it is of little use to milk producers. Good meadow hay, on the other hand, contains good nourishment, readily available, and is highly valuable for milk producing stock.

The use of the mower is also advantageous in removing or reducing grasses or plants that are more or less obnoxious, such as Sterile Brome, Silver, and Barley grass, that have troublesome grass seeds. These, when mown in an immature state and carted from the field, have less chance of reproducing so thickly, and thereby give the better grasses a greater opportunity to develop.

In conclusion, allow me to repeat three important factors relative to the management of pastures:—

1. Sow a mixture of grasses and clover seeds of proved vitality and suitable to your local soil and climatic conditions, and when sowing, give them every opportunity to thrive, similar as would be given to cereal crops.

2. Apply liberal dressings of fertiliser, at least 90lbs. 45 per cent. superphosphate annually.

3. Adopt a methodical system of grazing so that portions of the pasture fields are not over-grazed to the detriment of other portions.

An address, "The Clydesdale Horse," which was illustrated with lantern slides, was given by Mr. F. H. Francis, President of the South Australian Branch of the Clydesdale Horse Society.

#### CODLIN MOTH EXPERIMENTS.

The following paper was read by Mr. R. FOWLER, Manager of the Blackwood Experimental Orchard:—

During the past few years, since restrictions were placed by the English authorities on the importation of apples or other fruits carrying arsenical spray residue exceeding 0.01 grains per lb. of fruit, many efforts have been made to find means of control other than the use of arsenical compounds, more particularly in the last two or three sprays prior to harvesting, and of recent years the use of oils, particularly the so-called "white oils," has been brought rather prominently under the notice of growers.

Extensive experiments have been carried out in America and South Africa, as well as in New South Wales and Victoria, with more or less success, though with different conclusions. As the matter is one of great interest to growers, both from the point of view of the more efficient control of the codlin and the elimination from the cost of production of the heavy expense involved in wiping or otherwise removing the excess arsenical residue, the Chief Horticultural Instructor decided to initiate a number of experiments at the Blackwood Orchard with a view to testing, under local conditions, the use of "white oils" as possible ovicides in the control of codlin moth. It was also decided at the same time to test the relative effectiveness of the imported American oil known as "Volck," and an Australian production put on the market by Cooper Nephews' Ltd., under the name of "Alboleum," especially as the latter holds the advantage of being from 1s. to 1s. 6d. a gallon cheaper than the former.

In the previous season, 1928-29, when there was a very light crop of fruit, the infestation of codlin moth was very severe, being as high as 47 per cent. in some of our plots under the ordinary spraying programme of five sprays with Lead Arsenate. From the number of grubs caught in the bandages, where these were used in the spraying experiments last season, it seemed very probable that there would be a large carry-over of caterpillars to start a heavy Spring infestation this

season, but for some unexplained reason this was not so, if we may judge from the number of moths caught in the bait traps at the beginning of the season 1929-30. It would also seem as if some unknown parasite, or fungus, was responsible for the destruction of a large number of the over-wintering caterpillars. Whatever may have been the controlling factor, the fact remains that the codlin moths were not nearly so numerous in the early part of the season, judging from the numbers caught in the bait traps, as they were in the previous season, when we had a light crop of fruit for them to attack.

#### GENERAL NATURE OF CONTROL TESTS.

Seventeen spraying tests were carried out this year. They were designed with the idea of determining the most effective and economical method of dealing with codlin control under identical orchard conditions, and at the same time to find out if the oil treatment would prove efficacious, both in the control of the codlin and in the elimination of the arsenical residue from the fruit at harvest time. The tests included:—

1. Arsenate of lead and fluxit spreader.
2. Arsenate of lead and Summer oils combined.
3. Summer oil alone.
4. Arsenate of lead, two sprays, viz., one calyx and one cover, followed by three Summer oil sprays.
5. Arsenate of lead, two calyx sprays, followed by three Summer oil sprays.
6. Arsenate of lead without spreader.
7. Arsinette, which is claimed to be a combined Arsenate of lead and spreader mixture, two sprays followed by three Summer oil sprays.
8. Arsenate of lead with and without a calyx spray; and
9. The application of arsenical dusts.

Each test received five applications of spray with the exception of the test where the calyx spray was omitted, and in the dusting experiment, owing to the extreme difficulty of getting suitably calm weather, it was only possible to give four applications of dust. On all four occasions, however, the weather conditions were favorable for doing efficient work. The last application of spray was given on the 29th January. The intention was to have applied a still later spray had general conditions and evidences of codlin activity demanded it, but it was found very difficult to get the spraying outfit between the rows, owing to the spread of the limbs caused by the heavy crops the trees were carrying. From the small number of moths being caught in the bait traps in early February, and the absence of apples on the trees showing codlin injury, it appeared there was not much moth activity, and it was finally decided to omit it. From the results obtained it would certainly seem that another application of spray would not have been warranted, and would, in the season under review, have been a waste of time and material.

All applications of spray were made by the Writer himself, assisted by an experienced orchard hand, and every care was taken to perform the work as thoroughly as possible, both outside and inside the trees, which were good standard types for the Variety, each carrying approximately 8 to 10 cases of fruit, and in a few instances 14 to 20 cases. The ordinary orchard motor spray pump was used, and the ordinary "Friend" nozzle was substituted for the spray pistol to enable the operator to exercise a better control in the direction of the spray material. The amount of spray used—approximating to 2galls. per tree—was sufficient to thoroughly wet all portions of the tree. A pressure of from 175-200lbs. per square inch was maintained, and the spray was applied as a fairly coarse mist.

[illegible]

When a fairly large number of tests are being carried out, it is necessary to limit the number of Trees in each test to enable the applications to be made as near the proper time as possible with the facilities available, and in the tabulating of results, though the margin of error may be greater owing to the carry-over infestation from adjoining trees, it is, in our opinion, preferable in the final check up of results for the percentages to be computed from the actual crop taken from each tree in the test rather than from a portion of the crop from each tree, or from a selected number of trees in each test. A close study of individual tree records shows a wide variation of infestation under the same treatment, and where different varieties are included in the test, the same difficulty occurs, as the degree of infestation in the different varieties has been found to vary greatly. In test F., for instance, Cleopatras showed 7.51 per cent.; Dunn's, 4.74 per cent.; Jonathan, 2.96 per cent.; and Scarlet Nonpareil, 0.06 per cent. of infestation.

Owing to the abnormal weather conditions, the harvesting season under review was unusually extended, and it was feared that this might to some extent interfere with the results, as there was a danger, owing to the very dry conditions prevailing, that the later fruits would be exposed to infestation from a possible third brood of moths. This was not the case, however, and it is our opinion that the results obtained fairly accurately indicate the merits or demerits of the sprays used.

#### CODLIN MOTH TRAPPING RECORDS FOR 1929-30.

The first traps (six in number) were put out on September 30th in a block of pears close to the Office, and the first moths were caught on October 24th. The 48 traps from which the moth data for the season were taken were then put out and examined every seven days until March 10th. As previously stated, the catch was comparatively light right throughout the season. The Spring brood emerged in greatest numbers between October 27th and November 4th. Approximately five weeks later the first brood of moths appeared and fair numbers were caught in the traps, and again about six weeks later, February 3rd to 10th, the second brood moths appeared and were fairly numerous up to March 3rd. The lures used this season were a solution of molasses, 1 in 3 of water, fermented apple juice diluted with an equal volume of water, and a mixture of fermented apple and pear juice similarly diluted.

The best results were obtained with the molasses solution, and, as noted in previous years, this solution is far less destructive to beneficial insects, such as Ladybirds and Lacewing flies. The strength of this mixture has been maintained at 1-3, but we lean to the opinion that it could be reduced to 1 in 10 and still prove equally effective. It has the advantage over other lures in that it is readily procurable and can be always kept on hand.

A feature of the trapping this season has been the enormous number of boll worm moths of various species caught in the traps, particularly in the early part of the season, when it was a common occurrence to take 20 or more such moths from each trap. It is quite possible that their presence to some extent offered obstruction and thus interfered with the entry of the codlin moths into the traps. Examination of the codlin moths caught again showed, as in previous seasons, that about 50 per cent. were females, and of the females examined some were found to contain eggs, while others showed no signs of gravidity.

A previous experience seemed to show that where a few traps were used in a small portion of the orchard, the percentage of codlin injury was not less than where no traps were used. It was therefore assumed that the traps used in Tests A., B., C., and D. would not interfere in any way with the comparative value of the Tests, and the correctness of this assumption is seemingly supported by the results. The results of trapping Moths will be found in the following Table II.

## RESULTS OF SPRAYING TESTS.

All records were made by the writer with the capable assistance of N. R. Quinn (Assistant Orchardist at Blackwood), and a reliable member of the staff.

In calculating the percentage of codlin affected fruit, all fruit produced on the trees was examined carefully, including windfalls, which were gathered from time to time. Owing to the amount of work involved in attempting to arrive at a percentage by counting of infested fruits this method had to be abandoned in favor of a record for weight. This method we consider gives a fairly accurate idea of the wastage. No separate record was made to indicate whether the codlin had entered through the calyx or through the side, but it was an outstanding feature in the past season that most, if not all, the affected fruits had been injured by the larvae of the first brood moths, there being almost a complete absence of the second brood of caterpillars usually found freely entering the apples at picking time.

The fact that later varieties and even some fruits of early ripening varieties that were left on the trees owing to lack of size till the end of May showed practically no signs of infestation by this brood would seem to indicate that it did not appear in anything approaching its usual numbers. It would seem then that a large proportion of the first and probably most of the second brood grubs did not transform this season, and that fact may possibly offer an explanation should a very abundant first brood appear next season.

## ARSENATE OF LEAD AND VOLCK OIL TESTS.

## DISCUSSION OF RESULTS.

In Test A. arsenate of lead with fluxit added to the last three sprays was used; in Tests B. and C. arsenate of lead twice, Volck Oil three times; and in Test D. arsenate of lead in combination with Volck Oil; in Test B1 Volck Oil alone was used. From one year's records it would seem that the arsenate and oil mixture gave the best results from the codlin control point of view, only 0.61 per cent. of fruit by weight being rejected. From the viewpoint of arsenical spray residue, though analyses showed 5.1 grains of arsenic per pound, the fruits were badly covered and would all require cleansing. Test B1, Volck Oil alone, gave very good results from the control point of view, but the general appearance of the fruit (Jonathan), particularly as to color, seemed to be marred by the continual application of Volck Oil. This may have been due to the abnormal weather conditions, as practically no rain fell after December, and the oil seemed to hold the dust on the trees and fruit. The coloring was blotched and streaky and detracted very much from the general appearance of the Jonathan apples.

In Tests B. and C. two arsenate and three Volck Oil sprays, Test C., where the arsenate was used as two calyx sprays, gave slightly better results than Test B, which received a calyx and first cover spraying 10 days later. This result seems to emphasise the necessity for the calyx spray being done very thoroughly.

In Test A., where arsenate of lead alone was used for the first two sprays, and with 1lb. fluxit per 100galls. added to the last three sprays, the result could be considered quite satisfactory, the percentage of codlin being only 4.88 as against 5.43 and 3.85 in Tests B. and C. Analyses showed a much higher percentage of arsenical spray residue than the tolerance allowed in England and all these fruits required wiping or washing before packing.

It would seem, then, while Arsenate of lead alone and arsenate and oil mixtures gave good results, the arsenical spray residue adhering to the fruits was excessive. That two arsenate and three oil sprays will give good results as regards codlin control, and that the percentage of spray residue is considerably reduced in comparison with the preceding treatments. There was evidence of slight oil injury to a few fruits, but the loss was negligible. As in Test B1, the oil seemed to hold the dust on the fruit and trees, and to some extent the general appearance of the

fruit was marred. This might not occur in a year of average rainfall during the summer months. That oil alone applied five times will control codlin moth, but appears to injure the appearance of the fruit, particularly of colored sorts.

#### ARSENATE OF LEAD AND ALBOLEUM OIL.

These Tests E., F., G., and H. were a repetition of A., B., C., and D. with this difference, that Alboleum was used instead of Volck Oil, and the results were much the same. The lowest per cent. of codlin injury was in Test H., sprayed with the arsenate and oil in combination, but the arsenical residue was again higher than the British tolerance. Arsenate of Lead, two calyx sprays, followed by three oil gave slightly better results than a calyx and first cover followed by three oil sprays, and arsenate of lead with fluxit added also gave good results, but again the arsenical residue was excessive. In the comparison between Volck and Alboleum as possible ovicides for codlin control, Volck seems to have a very slight advantage, but so small as to be almost negligible, so that it can reasonably be inferred that the Australian product is equally as effective as the imported, viewed as a preventer of Codlin infection whatever its action may ultimately be proved to be.

In these tests four varieties of apples were used, and it is interesting to note that of the four varieties—viz., Cleopatra, Dunn's Seedling, Jonathan, and Scarlet Nonpareil—the Cleopatra used in these trials was shown to be the most susceptible to codlin injury, then Dunn's, followed by Jonathan, and lastly Scarlet Nonpareil; the latter variety being hardly attacked at all. It would be interesting to know the results obtained by other experimenters in this respect. There was slight evidence of oil injury as with the Volck, but only in a very few instances, and the appearance of the fruit generally was very good and clean.

Tests G. and H. were carried out on densely branched, unpruned trees, carrying heavy crops, but the results were equally as good as with the pruned trees.

#### TESTS WITH ARSENATE OF LEAD ALONE AND WITH SPREADER ADDED.

Results of Tests I. and J., with arsenate alone and with spreader (fluxit) added to the last three sprays, seems to indicate that some advantage was derived from the use of fluxit, but this cannot, in our opinion, be taken as a definite conclusion from the results of one year's work, as previous tests with casein spreaders over four years did not show any particular benefit from their use.

W. S. Regan, of the Research Department of the California Spray-Chemical Company, in his 1929 experiments found that Arsenate of Lead used alone had a slight advantage from the standpoint of control over Lead and Fluxit, and he concluded from the fact that in the Lead Fluxit combination test there was much increased worm work towards the end of the season, when spraying had ceased, that the combination, although building up a heavy coverage at the time when application is made, it weathers or flakes off more rapidly than is probably the case with the lead when used alone. In our tests this season we were only able to use the fluxit in the last three sprays, as the material did not come to hand in time for the calyx and the first cover spray. We hope to carry out further tests this coming season. No special analyses were made of the arsenical residue at picking time, but in both tests most of the fruit required wiping before packing.

#### TESTS BETWEEN ARSINETTE AND ARSENATE OF LEAD WITH FLUXIT COMBINATION.

Arsinette, which is claimed to be Arsenate of Lead in which the spreader is incorporated with the lead, is made in Australia by Cooper Nephews. Fluxit is a spreader manufactured in America. The result of the test seems to be in favor of arsinette, Cleopatras showing only 3.14 per cent. of Codlin in Test L. as against 6 per cent. in Test K., and Esopus Spitzenberg 4.92 per cent. as against 9.72 per cent. Arsinette mixes very readily, but violent agitation as, for instance, the propeller type used in some spray pumps causes it to froth up badly.

### TESTS WITH ARSINETTE AND ALBOLEUM OIL v. ARSENATE OF LEAD WITH FLUXIT AND VOLCK OIL.

In Tests M. and A. Arsinette and Alboleum gave slightly better results than the Arsenate of Lead-Fluxit and Volck, Cleopatras showing only 3.9 per cent. of codlin as against 4.88 per cent.; but as there were only two trees under treatment in Test M. as against 12 in Test A., there can be no fair conclusion reached. Arsinette and Alboleum Test M. also gave slightly better results than the Lead and Fluxit and Alboleum. Test F., Cleopatras showing 3.9 per cent. codlin as against 4.66 per cent., Jonathans 3.23 per cent. as against 4.86 per cent.; analyses for spray residue showed 1.05/100 grains in Test F., no analyses for spray being made in Test M., but the apples showed practically no signs of spray residue when packed. Slight traces of oil injury were noticed on a few fruits, but very little damage resulted.

### TESTS WITH ARSENICAL DUST AS AGAINST WET ARSENICAL SPRAY.

The 1929-30 tests again demonstrated, as in the previous four years, that dusting for codlin moth control did not give the same satisfactory results as the wet spray. Test N., dusted four times, showed 16.31 per cent. of codlin injured fruit. Test O., sprayed four times, 6.66 per cent.; and Test P., sprayed five times, 5.12 per cent. Analyses for spray residue showed slightly in favor of dust, viz., 0.95/100 grains as against 1.04/100 grains per lb. It is generally considered that effective control of codlin moth by means of sprays depends on the spray programme being carried out at the right time, and as dusting is dependent so much more than wet spraying on weather conditions, it is here where the greatest difficulty comes in. Last season it was difficult to get a calm day at the right time, and it was time for the third dusting before we got the second on, though on the actual days when the dusts were applied conditions on the whole were favorable for a proper distribution of the testing material.

The omission of the calyx spray in Test O. would seem to have resulted in a slight increase in codlin injury, 6.66 per cent. as against 5.12 per cent. where the calyx spray was applied. This result, not very convincing, coincides with previous experience.

### COMPARATIVE COSTS OF SPRAYS.

In the production costs of a case of Apples, spraying is a very large item, and the cost of spraying material has to be carefully considered before a change of spray programme can be considered. In the following Table an attempt is made to show the approximate costs connected with this year's tests in regard to material only:—

|                                                                                      |                  |
|--------------------------------------------------------------------------------------|------------------|
| 100galls. spray, using 4lbs. lead to 100galls., with lead at 10d. costs              | 3s. 4d. per 100. |
| 100galls. spray, using 2galls. Volck to 100galls., with Volck at 8s. 6d. costs       | 17s. per 100.    |
| 100galls. spray, using 2galls. Alboleum to 100galls., with Alboleum at 7s. 6d. costs | 15s. per 100.    |

It will be noticed from the Table following that there was little difference in the loss per acre from the use of five sprayings with arsenate of lead alone and arsenate twice and oil three times, but a great difference in the cost of material per acre. Against this must be placed the cost of wiping or washing the apples before packing, a costly operation running into 3d. or 4d. a case approximately.

In D. and H. the losses per acre were considerably reduced, but at such a high cost for spraying material that the benefit derived was more than lost again without, in this case, any advantage as regards spray residue, but rather the reverse is true, as the lead arsenate and oil combined not only showed more residual arsenic than arsenate alone, but the combination was much harder, if not actually impossible, to remove by ordinary wiping methods.

TABLE III.—*Showing Details of Spray Material Costs.*

| Description of Spray.                                                        | Relative Cost per Test on 100-gall. Basis, Sprayed Five Times. | Relative Cost per Acre Sprayed Five Times with 150galls. Spray at each Application. | Cost per Case of Fruit Calculated at 300 Cases per Acre. | Loss Due to Codlin Injury as shown by Results. | Loss per Acre due to Codlin, Calculated at 3s. per Case, at 300 Cases per Acre. |

## SUMMARY OF RESULTS FOR SEASON 1929-30.

To sum up, it would seem that from one year's results:—

1. That this season arsenate of lead with the addition of fluxit in last three sprays gave very satisfactory results.
2. That arsenate of lead alone was only slightly less satisfactory than arsenate of lead and fluxit.
3. That arsenate of lead, two calyx sprays and/or calyx and first cover, followed by three oil sprays, using either Volck or Alboleum, gave good results and reduced the arsenical residue trouble.
4. That the best results from the standpoint of codlin control were obtained by the use of the lead arsenate and oil combination, but that the present costs of these spraying oils seem to be almost prohibitive.
5. That the lead arsenate and oil combinations when mixed before spraying left the highest per cent. of arsenical residue per pound of fruit, and that it was found most difficult to remove.
6. That the lead arsenate and oil combinations probably owe their extra efficiency to the fact that they make a heavy coverage on the fruit, which is not readily washed off by rain or rubbed off by wind action.
7. That a slight injury to the fruit follows the use of Volck and/or Alboleum, but that the damage is not serious.
8. That Volck oil alone will control codlin moth, but that it seems to inhibit to some extent the color formation of the skins of red apples and causes a certain amount of rustiness, thereby detracting considerably from the general appearance of the fruit.
9. That from the viewpoint of effectiveness in codlin control, Alboleum may be expected to give just as satisfactory results as Volck.
10. That "Arsinette" alone gave very good results, but a suspicious amount of what may be arsenical residue was noticeable on the fruit at packing time.
11. That in a dry season like the one just experienced, applications of oil tend to collect the dust on foliage and fruit to the detriment of both.
12. That arsenical dusts do not seem to give satisfactory results in codlin control.
13. That it is not advisable to omit the calyx spray.
14. That, on the whole, in the apple growing areas in this State, there was a heavy crop of fruit with a naturally light infestation of codlin moth during the season under review.

Data in connection with control tests is given in detail in the following Table IV.

TABLE IV.—Detailed Results of 1929-30 Spraying Tests for Codlin Moth, Blackwood.

| Test O Variety.                                                                   | Spray Schedule.                                                                                                                                      | Dates Applied.                  | Total Crop per Test, in Lbs. | Average Crop in Tree in each Test. | Total Weight of Apples with Codlin String or Grubs per Test. | Average Weight per Tree of Apples with Codlin String or Grubs. | No. of Codlin Larvae Caught in Bandages per 100 lbs. of Fruit. | No. of Trapped Moths in Test. | No. of Codlin Grubs Caught in Bandages per Test. | Per Cent. of Codlin per Test. | Grains of Arsenic, AS <sub>4</sub> O <sub>6</sub> , per Lb. of Apples. |

|                                                                               |                                                                                                                                                               | 31/10/29       |                                   |                                    |                                                        |                                                                 |                                                                 |                                       |                                                   |                                |                                                                        |
|                                                                               |                                                                                                                                                               | 26/11/29       |                                   |                                    |                                                        |                                                                 |                                                                 |                                       |                                                   |                                |                                                                        |
|                                                                               |                                                                                                                                                               | 16/12/29       |                                   |                                    |                                                        |                                                                 |                                                                 |                                       |                                                   |                                |                                                                        |

(To be continued.)

## TOMATO DISEASES IN SOUTH AUSTRALIA AND HOW TO CONTROL THEM

with special reference to Glasshouse Tomato Culture.

[By GEOFFREY SAMUEL, M.Sc., Plant Pathologist, Waite Agricultural  
Research Institute, University of Adelaide.]

[Continued from page 272, *Journal of Agriculture*, October, 1930.]

### BACTERIAL WILT.

*Description.*—Bacterial wilt is sometimes called “white disease” by South Australian growers, on account of the fact that the young green fruit ceases to develop, and becomes rather white, dry, and puffy, and drops off easily. The disease is not common in South Australia. It is most easily

FIG. 14.—Leaf from plant affected with Bacteria Wilt, showing sudden collapse of some leaflets while still green.

recognised by its effect on the leaves. Several leaflets will suddenly commence to shrivel and hang down limp, still retaining their green color, however, while other leaflets on the same leaf may still be perfectly normal (Fig. 14). Often the leaves up one side of a plant will become affected

first. In bad cases the whole plant begins to wilt or droop. If the stalk of an affected leaf be broken across a small amount of a greyish slime may be noticed at the broken end. This sliminess and a brownish discoloration of the wood may be traced right down the stem and into the roots in the later stages.

*Cause.*—The disease is due to bacteria, which may infect the plant through wounds, either on the roots or on stems and leaves. It is the multiplication of these bacteria or germs inside the plant in enormous numbers which forms the slimy substance, blocking up the water-conducting vessels and finally causing a wilt.

The name of the bacterium has not yet been determined for South Australian specimens. In America there are two bacterial diseases of tomatoes, the Brown Rot or Bacterial Wilt (caused by *Bacterium solanacearum*), and the Grand Rapids disease (caused by *Aplanobacter michiganense*). In some respects the South Australian disease resembles the latter more than the former. At the time it was noted, in 1926 and 1927, however, there were no facilities for determining the organism, and in the last two years it has not been seen. If any grower gets plants which he suspects of being infected by this disease, the Waite Institute would be glad if he would send some specimens. Further details on the way in which bacteria cause disease are given on page 255 (October issue).

*Control.*—Once the disease appears in a glasshouse great care should be taken to prevent it preading. The bacteria are such minute living organisms that tens of thousands of them could stick on the fingers after handling a diseased plant. It is advisable to pull out and bury or burn affected plants as soon as seen, and to wash the hands well with soap immediately afterwards. Cease pruning for 10 days to allow plants which may be already infected to show up, and pull out and destroy them as they are seen. Cutting off affected leaves scarcely ever checks the disease, and it is usually preferable to pull the whole plant out straight away. If affected leaves are cut off, the knife, hands, &c., should be washed with soap as before.

In the cases which have occurred in South Australia the disease has not always re-appeared in the same houses the following year. The bacterium causing the disease is not very long lived outside the plant, and the high summer temperatures in Adelaide glasshouses in February when the houses are empty may well have some sterilising effect, especially if the soil is allowed to dry out thoroughly. It would be advisable to give extra careful attention to the destruction of plants at the end of the season, and use fresh soil for next year's seedbeds if an outbreak of the trouble has occurred. Spraying or dusting is of practically no value in checking this disease.

#### “DAMPING-OFF” OF SEEDLINGS.

*Description.*—“Damping-off” is a disease which is very easily recognised. The stem of the young seedling becomes constricted just about ground level, and the affected plant usually topples over, most frequently while the leaves are still healthy and turgid (Fig. 15).

The disease can affect very young seedlings which have only just come up, and sometimes big patches in seedbeds may be seen in which the seedlings have just toppled over and died, especially in cases where the seed has been sown too thickly. At other times pricked-out seedlings

several inches high are attacked, as shown in the illustration. Larger plants are rarely affected. Fortunately, however, tomatoes are not as subject to damping-off trouble as are many other seedlings.

**Cause.**—This disease is caused by a parasitic fungus (*Phytophthora parasitica*, or sometimes other fungi, *Phytophthora cryptogea*, *Pythium*, or *Rhizoctonia*) attacking the stems of the seedlings at ground level. The fungus can live in damp soil, but can also attack seedlings vigorously when the right conditions are present. The conditions which favor the fungus are continuous dampness of the surface soil, warmth, and succulent plant stems such as are produced when seedlings are overcrowded. If seedlings are overcrowded it is also easier for the fungus to grow from one to the other, and the condition of the surface soil remains shaded and moist too long. It is under such conditions that seedlings may go down in dozens, and the infected patches in the seedbeds can be seen growing larger every day.

FIG. 15.—Seedling attacked by "damping-off" fungus, showing the construction of the stem at ground level.

Figure 16 illustrates the way in which the fungus threads penetrate the cells in the stem of the seedling. It will be seen that the fungus bores right through the cell-walls, and grows through the cells, absorbing food material from cell-sap and other materials present. The fungus threads branch and grow into more cells, so that the part of the stem which is attacked soon begins to collapse. The collapse of the stem-tissues follows the continued growth of the fungus, and when the latter has grown right round the stem the typical constriction at soil level results, and the plant topples over owing to the destruction of its supporting tissues. Fungus threads then grow out from the diseased tissue through the moist soil, and attack surrounding seedlings in the same way.

The fungus can spread to new positions in the seedboxes by minute swimming spores formed in egg-shaped swellings on branches of the fungus threads and then liberated into the surrounding water. These cannot swim far, but can be washed or splashed considerable distances during watering. Thick-walled spores are also formed later, which can resist drying and carry the fungus over from one season to another in the soil.

*Control.*—It will be seen from the above that the following are the important points in the control of damping-off:—

- (1) Do not use soil for seedbeds which has previously had the disease in it, for the fungus may still be present in the soil. Infected seedbed soils can be rendered safe by sterilisation with steam, but the apparatus required for steam sterilisation is usually not available to South Australian growers, who would find it cheaper to replace the soil in the seedbeds (very thoroughly). If it is particularly desired to sterilise infected soil this can be done with formalin. Details will appear in a subsequent issue.
- (2) Do not overcrowd the seedlings.
- (3) Do not over-water.

FIG. 16.—A "damping-off" fungus invading the cells of a seedling about ground level. The fungus has penetrated in at a breathing pore and can be seen growing within the cells inside, which will soon collapse. At this magnification the whole stem would be about 2ft. or 3ft. across. Plant cell-walls black; fungus dotted.

- (4) If the disease does appear, pull out infected seedlings as soon as they are seen, and water the seedbeds with Cheshunt Compound (see page 162, September issue; details of this Compound will appear later).

In England the water supply has sometimes to be considered as a possible source of infection, especially when drainage may come from neighboring properties on which tomatoes are grown. No cases have yet

come under notice in South Australia, however, in which infection could be traced to the water supply. In fact tomato seedbeds here are very free from damping-off troubles, and in cases where they have occurred it has usually been because one or more of the above points has been neglected. The pricking out of seedlings into one of the glasshouses before planting out is a practice which might easily favor the disease.

The following extract from Dr. Bewley's book on the "Diseases of Glasshouse Plants" shows how valuable Cheshunt Compound may be in checking off damping-off disease:—"During an epidemic at one nursery the grower replanted two houses four times, and each time lost practically the

FIG. 17.—Tomato plant (tall variety) wilting in the daytime owing to the roots and stem being invaded by the *Verticillium* wilt fungus. If the roots or the stem are cut open the wood inside is seen to be discolored a light brown by the fungus.

whole of his plants. When replanting for the fifth time the soil was treated with Cheshunt Compound, with the result that only four plants were lost out of 2,000."

#### VERTICILLIUM WILT.

**Description.**—This disease, which used to be called "Sleepy disease," is unfortunately fairly common in South Australian glasshouses, especially in the more clayey soils. It is primarily a disease of the roots and the water-conducting vessels of the stem, so that the symptoms shown by the

tops of the plants are secondary, due to the trouble down below. The symptoms vary considerably, depending to some extent on the soil, the variety, and the growing conditions.

Occasionally plants can become infected while still fairly young, and in this case they become "dull" or "sleepy" in appearance, seem as if they can't grow ahead properly, and sometimes acquire a purplish look. If they are pulled up, the ends of the roots will be found to be brownish and dying back, and the wood inside the roots discolored brownish.

More often, however, it is not until the plants are from 1ft. to 2ft. or more in height that they begin to show signs of becoming "sleepy." The growing point does not look vigorous and succulent, but becomes rather thin and spindly. The lower leaves begin to turn yellow gradually and may shrivel and brown from the margins. This occurs most frequently with the variety Early Dwarf Red on the more clayey soils, and as the yellowing leaves are usually pulled off, the lower truss or two of fruit is left bare. With tall varieties, leaf yellowing may not occur so much, and an actual wilting or drooping of the plant in the warm part of the day take place (Fig. 17), the plant recovering again at night.

In all cases, and in the later stages especially, if the root and base of the stem are slit open with a clean, sharp knife, it will be seen that the wood is discolored a light brownish color. Sometimes this discoloration of the wood runs right up the stem for some feet.

*Cause.*—The cause of this disease is a fungus (*Verticillium albo-atrum*), which lives in the soil and attacks the roots of the plants first. The fungus penetrates to the centre of the root, for it seems particularly adapted to living in the wood or water-conducting vessels (Fig. 19A). It grows upwards within the wood vessels, from the root into the stem, and finally extends in the wood almost throughout the entire plant. It is probably some substance secreted by the fungus which causes the wood of the plant to turn brown. It is partly the blocking up of the water-conducting vessels by the threads of fungus, and partly perhaps the poisoned substances which the fungus forms, that causes the plant to gradually wither from below upwards.

The fungus has two methods of lasting over from season to season and spreading in the soil. One is by the formation of spores in immense numbers on the base of the stems of infected plants. In late stages of disease, and when moisture conditions are favorable, the fungus grows out from the wood and forms spores in little heads on the ends of short branches arranged in rings or whorls as in Fig. 19B. These may be present in such numbers that they are visible as a white mouldy patch near the base of the stem (Fig. 18). The small spores can blow away or get washed away, and are capable of starting the fungus in a new situation.

In South Australia, however, these spores are not very often found, perhaps because of the dry summer heat. The fungus probably lasts over from season to season mainly by little resistant pieces of fungus tissue formed from interwoven fungus threads with thick walls. These are formed in considerable numbers in the diseased roots, and when a rotten root is pulled up it is impossible to avoid leaving many small rotted parts containing the fungus behind in the soil (Fig. 18). It is probably mainly from such bits of tissue left in the soil after pulling up the plants that the fungus lasts over from season to season. When moisture comes again at planting

FIG. 18.—The base of the stem of a plant which died from *Verticillium* wilt and which was left in the house. Roots all rotted away and a white mouldy growth (a) just above soil level where thousands of spores are being formed by the fungus (see Fig. 19 b-d).

FIG. 19.—(a) Fungus threads of the *Verticillium* wilt fungus growing within the cavity of one of the water-conducting vessels of a tomato stem and blocking it up. Greatly magnified; compare with Fig. 1 (b) showing a water-conducting vessel blocked up by bacteria.

(b) Spore-bearing branches of the *Verticillium* wilt fungus formed in immense numbers at the stem-base of a plant which has been killed by the disease and left in the moist atmosphere of the glasshouse (see Fig. 18). The round globules are masses of spores embedded in slime, and this quickly dissolves in water and sets free the spores as in (c). Single spores shown in (d). Magnified 800 times.

time these bits of fungus tissue germinate, and any which come in contact with the new young seedlings may infect them and reproduce the disease again.

**Control.**—The control of *Verticillium* Wilt is very difficult in glasshouses of the type of those in South Australia, in which no heat is available. It is not possible to steam sterilise the soil every few years or to exercise any control over the temperatures in the houses during growth. This is particularly unfortunate in the case of *Verticillium* Wilt, for it has been shown in England that the disease can be fairly well controlled by raising the temperatures of the houses above 77deg. and applying a light shading of whitewash.

As usual, it is preferable to prevent a disease appearing rather than to try and check it once it has appeared. What we need, therefore, is some way of getting rid of the fungus from the soil other than steam sterilisation before the year's planting begins, if possible. This may not be as hopeless as it sounds. As was suggested before, the high summer temperatures in Adelaide might well have some partial sterilising effect on the soil during the later summer months when the houses are empty. Such an effect could probably be considerably helped by judicious treatment of the soil. If the old roots, &c., of last year's crop are pulled out as quickly as possible, and the house dug over and then left to dry out during one or more "heat spells," and then the process of flooding and digging repeated, the alternate wetting and drying might aid considerably in ridding the soil of root-rot fungi. Of course, if the previous year's crop was not infected treatment more than once would not be necessary, but the digging two or even three times is suggested as a method worthy of trial if many of the plants were affected with *Verticillium* Wilt in the crop just pulled out.

Having prepared the soil to the best advantage the young plants should be given the best possible conditions for growth according to the first few chapters of this bulletin. Dr. Bewley has shown that in the case of *Verticillium* Wilt, unlike most other diseases, it is not the succulent plants which get the disease worst, but the plants of harder and backward growth which have suffered some check or have not the best growing conditions which get the disease.

Returning once again to the subject of temperature, the checking effect on the disease of a bright and sunny spring and early summer is noticeable in South Australian glasshouses. We have had several such seasons lately, and *Verticillium* Wilt has not been as prevalent as it was formerly. In cases where it has occurred in spring it has disappeared considerably as the weather warmed up. It is doubtful whether shading for the disease is advisable under our conditions, for it would reduce the temperature, and this could not be kept up by more heat from the boiler, as in England.

Summarising the measures for control of *Verticillium* Wilt:—

- (1) Prepare the soil early and well, and let it dry out once or twice if the disease was present before.
- (2) Plant with vigorous seedlings and keep them growing well.
- (3) If the disease appears, heap soil higher up round the base of the stems to allow new roots to form, do not water too heavily, and keep the house as warm as possible.

## OTHER ROOT-ROT DISEASES.

*Description and Causes.*—Although *Verticillium* seems to be the main fungus responsible for root-rot diseases in the glasshouses of the Adelaide district, there are others which have been met with on a number of occasions. Further research work will have to be done to find out just how important these are, and what the conditions are which favor them. In most cases the symptoms of these root-rot troubles are much the same—spindly or poor growth, sometimes with wilting of the plant in the warmer part of the day, leaves yellowing from below upwards, and roots when pulled up found to be dying back from the tips often with a brownish discoloration of the wood inside. Affected plants, of course, finally die prematurely.

*Black Dot Root-rot* (caused by the fungus *Colletotrichum atramentarium*).—This is a disease which can be recognised by the naked eye in its later stages, owing to the presence of small black dots in the wood and bark of the rotted roots. When plants are pulled up the outer part of the roots often strips away, leaving the central strand of wood in which the minute black specks of the fungus can be seen (Fig. 20).

FIG. 20.—Roots of a plant affected with Black Dot root-rot, showing how the bark strips away from the wood; also the small black specks of the fungus in the rotten wood.

In England this fungus has been found to cause more damage when the soil conditions are somewhat dry, especially if cold as well. The fungus works very slowly, as a rule, and often becomes evident only because the top fruit-trusses fail to swell properly. In one case, however, an example of a severe effect of this fungus in an early stage was obtained when a hail-storm broke in the roof of a glasshouse recently planted with young plants. The plants were exposed to the cold for only two or three days, but when a new roof was put on they did not make any headway, remaining stunted and rather purplish in color. When pulled up the roots were found to be rotting back and brownish inside, and a scientific examination showed that they were affected by the Black Dot fungus.

(To be continued.)

## EELWORMS (*Heterodera schachtii* Schm.) AFFECTING CEREALS IN SOUTH AUSTRALIA.

[By J. DAVIDSON, D.Sc., F.E.S., Waite Agricultural Research Institute, University of Adelaide.]

In the August number of this *Journal* for 1928 Mr. G. Samuel gave some observations on "Two 'stunting' diseases of wheat and oats." Affected plants were recorded from unhealthy patches occurring in these crops in various localities in South Australia. Examination of these plants showed that eelworms, which were referred to as possibly a species of *Aphelenchus*, were present in some cases. In others a fungus disease, apparently due to a species of *Rhizoctonia*, was found. These two parasites were evidently important factors affecting the condition of the plants. Mr. Samuel discussed the matter with me when I came to Adelaide in 1928 and kindly placed at my disposal the information he had obtained regarding eelworm infestation.

Since October, 1928, I have been able to make further observations regarding the species of eelworm concerned. It has been found that it is a species of *Heterodera*, namely, *H. schachtii*, and that it occurs on oats and wheat and to a less extent on barley, in various districts in South Australia.

Fig. 1.—An affected Oat plant with female Cysts on roots—September, 1930.

In September last Mr. A. B. Hickinbotham observed the widespread distribution of the pest in the Roseworthy district, and invited me to visit the area. Mr. Hickinbotham has now made a survey of the distribution of the pest in that district, and his valuable observations emphasise its importance in relation to cereal crops.

*Heterodera schachtii* is known as a pest on roots of oats in Scandinavia and Holland; also, to a less extent, on wheat and barley. It has been called the *Oat eelworm* in Denmark, so I have adopted this popular name, but it is clear that other cereals are affected by its attacks,

I.—RECORDS OF THE OAT EELWORM (*Heterodera schachtii*) ON CEREALS IN SOUTH AUSTRALIA.

So far as I am aware there is no published record of this species attacking cereals in South Australia. In an article by Mr. W. J. Spafford (*Journal of Agriculture, South Australia*, January, 1919) on "Trouble affecting cereals in the Penola district," there are several remarks regarding eelworms, but there is no definite evidence that this species was present. Mr. Spafford has very kindly sent me notes of references to eelworm attack on cereals, taken from the filed records in the Department of Agriculture dealing with diseases of crops in the State.

In most of these records, however, it is not possible to say definitely from the information available whether the species which we are now discussing was present. As long ago as 1906 barley plants grown at Roseworthy Agricultural College were sent to Mr. D. McAlpine, Plant Pathologist in the Department of Agriculture, Victoria. The following extract is taken from Mr. McAlpine's letter, dated August 15th, 1906:—  
" . . . The roots of some of the worst specimens were first washed, and then the swellings on the roots, &c., looked suspicious. On examining the very butt of the stems eelworms were found, and I have no doubt but Nematodes are the cause of the trouble . . . " The indication that *Heterodera schachtii* might have been present is suggested by the reference to the "swellings on the roots, &c."

Fig. 2.—Mature female of the Oat eelworm.

In August, 1918, a sample of wheat plants received from Mr. H. W. Tossell, of Maitland was reported on by Professor T. G. B. Osborn, as follows:—"The wheat is infected by a parasitic worm which lives inside the root tissues, causing a knot disease . . . Attempts to isolate a fungus or bacterium from the tissues gave uniform negative results." Evidently this was a species of *Heterodera*, and doubtless *H. schachtii*. In October, 1922, wheat (var. Nugget and Major) and oat (Algerian) plants from different fields on Mr. H. W. Tossell's farm at Maitland were reported on by Professor T. G. B. Osborn on October 18th, 1922, as follows:—"The trouble here is eelworm, not fungi. The wheat especially being badly infected with galled roots and cysts easily seen. I have shown the specimens to Mr. O. W. Tiegs, Lecturer in Zoology, who says the worm is *Heterodera schachtii*, not *H. radiculicola*."

In August, 1926, wheat plants received from Narridy and Paskeville were identified by Mr. Samuel as affected by eelworms, cysts being found on the roots. During September wheat and oat plants from Maitland were found to be similarly affected.

Further records were obtained by Mr. Samuel during 1927, 1928, and 1929. There is no doubt that the species concerned in these earlier records was the same as that diagnosed from later affected samples, namely, *Heterodera schachtii*. Samples of affected wheat and oat plants collected at Murray Bridge in October, 1928, were sent by the writer to Dr. T. Goodey, Institute of Agricultural Parasitology, St. Albans, England. Dr. Goodey reported that cysts of *Heterodera schachtii* were present on the roots of both the wheat and oat plants.

The records listed below, from 1926 onwards, have been definitely established by examination, either by Mr. Samuel or myself, of affected plants obtained from the various districts, chiefly through the agricultural instructors. Although the earliest definite record is given as October, 1922, it is evident, considering the distribution of the pest, that it has been affecting cereal crops in this State from an earlier period.

| Year.     | Month.         | District.              | Crop.                                                                 |

## II.—THE OAT EELWORM IS FOUND ON CEREALS IN OTHER COUNTRIES.

*Heterodera schachtii* was found on the roots of oats by Kuhn in 1874, and it is well known as a pest of oats in Denmark. In that country wheat is stated to be much less affected than oats, and rye seldom affected. It is also recorded on oats in Holland, and barley in Scandinavia and Holland. In 1926 Russel recorded an eelworm from the roots of wheat in Saskatchewan, which, from the published information, apparently resembles *H. schachtii* in its behaviour on the roots of the plant. It is, however, stated by Thorne (*Scientific Agriculture*, 1928, vol. 8) to be a new species, namely, *H. punctata*.

III.—*Heterodera schachtii* IS AN IMPORTANT PEST IN SEVERAL COUNTRIES.

In addition to cereals this eelworm is a serious and widely distributed pest of sugar beet in Europe. The species was in fact first discovered on the roots of sugar beet by Schacht in 1859. In 1913 it was found on potatoes in Germany, and is now known to be a pest of that crop in parts of England and Germany.

Fig. 3.—Young larva of the Oat eelworm.

In addition to the above crop plants it has been recorded from a number of other plants, including certain weeds. It is generally accepted, however, that distinct races or strains of the species occur, each strain being restricted to a limited number of these host-plants.

IV.—STRAINS OF *Heterodera schachtii*.

There is considerable evidence to show that distinctive strains of the eelworm occur, each strain having its own distinct range of host-plants. In Denmark, for instance, the strain attacking sugar beet is present and is considered to be distinct from the strain found on oats. Moreover, the other host-plants, such as weeds, &c., are not the same for the two strains.

This is a question of great importance in considering the practical aspect of the problem, and it is necessary to find out the range of host-plants on which the South Australian strain occurs.

It will be seen in a later paragraph that the soil is the source of infection. The behaviour of the eelworm population in the soil towards the crop grown on it, depends upon the crop (host-plant) with which earlier generations of the eelworm have been associated. Long association with particular host-plants appears to result in a specialised strain which become less fitted to succeed on certain other plants.

The available records from South Australia indicate that oats and wheat are particularly attacked, and barley to a less extent, but further records are required. Investigations in Denmark show that oats especially suffer from the pest, but wheat and barley are also to some extent susceptible. Nilsson-Ehle (*Hereditas*, 1920) found that certain varieties of barley are resistant, and that this character is hereditary. Experiments showed that where oats were grown in eelworm infected soil, following resistant varieties of barley, the yield of the oat crop was greater than after susceptible varieties of barley. The explanation appears to be that with the susceptible varieties of barley the eelworm population in the soil was increased, whereas with the resistant varieties on which the pest failed to develop, it was decreased.

These results indicate a promising line of investigation in relation to the problem in South Australia, and the first step should be the systematic collection of data regarding the intensity of attack on wheat, oats, and barley, and on different varieties of these cereals.

Fig. 4.—An affected Wheat plant (September, 1929.)

#### V.—LIFE HISTORY OF THE OAT EELWORM (*Heterodera schachtii*).

The only stage of the worm which is visible to the naked eye is the white distended female found attached to the roots of affected plants (Fig. 1). When full grown the female is about 1/25th inch long (Fig. 2). Its head end is firmly inserted into the tissues of the root. The whitish lemon-shaped body is greatly distended, owing to the large number of eggs it contains. When the female dies the body remains surrounding the eggs, thus forming an egg case or cyst, which becomes darker and eventually drops off into the soil.

If the conditions in the soil are unfavorable these cysts may remain dormant for many months as brown, resting cysts.

When conditions in the soil are favorable, particularly as regards moisture and temperature, minute, active worms about 1/70th inch long hatch out from the eggs and emerge from the cysts into the soil (Fig. 3). They are attracted to the roots of the host-plant apparently by the influence of secretions given out from the roots into the soil. They bore into the delicate tissue of the fine roots and then undergo further development. At this stage they differentiate into males and females.

Fig. 5.—Affected Oats, var. Early Burt (October 19, 1929.)

The females gradually increase in size, and, feeding on the juices of the root tissues, stimulate the latter to abnormal growth which results in the knotted appearance of affected roots (Fig. 1). As the females increase in size the body is forced out through the epidermis of the root on to the surface. The head end remains firmly fixed in the tissues, on the juices of which the females continue to feed. From this stage onwards the white, swollen female worms may be easily seen on affected roots. They are now ready for fertilisation by the male. After fertilisation the females greatly increase in size owing to the development of the numerous eggs, and become the conspicuous,

whitish, lemon-shaped bodies found on the roots. The length of the complete life cycle from the egg to the sexually mature adult varies according to the conditions, but is stated to be about four to five weeks.

The *males* behave differently from the females. After undergoing development in the root tissues they bore their way out through the epidermis into the soil as normal thread-like worms about 1/25th inch long. They seek out the females on the roots and fertilisation takes place.

#### *The Cysts.*

The egg sacs, or cysts, may contain 100 or more elongate eggs. During the growing season the conditions of the soil are suitable for the development of the embryos in the eggs, so that more than one generation of the worms may develop during that period. Female cysts have been noted on the roots of wheat and oats in South Australia at various times from April to October, but it is not yet possible to say how many generations of the worm occurs during the season. Doubtless the dry summer months are passed through in the soil in the resting cyst stage. The cysts are hygroscopic and swell up with moisture but shrink under dry conditions. With the beginning of the winter rains in April the conditions are suitable for the development of the eggs, and the young larval worms appear to emerge from the cysts at the time when the young cereal plants have started to grow.

The eggs in a resting cyst apparently do not hatch all at the same time, and it has been stated (Fuchs, 1911) that after five years in clean fallowed ground cysts may contain young. Research is necessary to find out what is the viability of the cysts under fallow conditions in South Australia, also the influence of soil temperatures and moisture on the hatching of the eggs and the length of time taken to complete development.

#### VI.—SYMPTOMS OF PLANTS ATTACKED.

The presence of the whitish swollen females or lemon-shaped cysts on the roots is a sure guide to affected plants. The early stages of the worm may be found by dissecting the root tissues, but in my experience they are not easy to find, and I have only obtained isolated individuals in a few cases. In the absence of these stages however, affected plants may be diagnosed by the abnormal root development. As seen in fig. 4, young wheat plants have nodular thickenings on the roots from which numerous lateral roots are given off. Owing to this abnormal growth the root system sometimes consists of a dense mass of delicate superficial rootlets. With oats (Fig. 5) the knotted character of the roots is often more pronounced. The plants appear to be attacked soon after root development begins, but the characteristic white females are not evident until a few weeks later. When the crop is a few inches high, weedy patches may be noticed in which the plants are thinner, shorter, and in general have an ill-nourished appearance. These patches are often referred to as "no-growth patches." Such plants have often been found attacked by the eelworm. The occurrence of these patches, however, cannot be considered as always due to this pest. Foot-rot fungi may be a contributory cause. A water-logged condition of the soil in local depressions may also result in "no-growth" patches.

My observations show that the actual effect of the eelworms on the plants as judged by their above-ground appearance varies considerably, so that with a general infestation over a paddock the crop will look patchy. Plants showing apparently normal growth may have female cysts on their roots as well as poor, spindly, weak plants. The damage to the roots due to the activity of the worms undoubtedly affects the growth of the

plants. The root system tends to be shallower, and is, therefore, more susceptible to changes in soil moisture. The chances of obtaining adequate nourishment are reduced. Indirectly, therefore, affected plants show the effects of poor nutrition.

In a particularly heavy infestation the growth of many plants may be completely checked, resulting in a partial failure of the crop. The effect will be particularly marked if other adverse influences are affecting the growth of the crop. Provided conditions for growth are good, the check to the root system of the plants by a normal or light infestation of the eelworm may not be obvious in the general appearance of the crop. With vigorous development of new roots and the relatively large root system of well-nourished plants, the latter are able to make progress against the attack. In this respect it has been observed that late sown crops appear to suffer more heavily than early sown.

It is evident that eelworm attack affects the yield of the crop to a greater or less extent. The loss is doubtless greater in some seasons than in others, due to the influence of varied seasonal conditions on the growth of the crop and the intensity of the eelworm infestation.

#### VII.—CONTROL MEASURES.

There appear to me to be three lines of attack along which practical control measures may be developed:—

- (a) Cultivation methods.
- (b) Rotation.
- (c) Varietal differences in susceptibility to the attack.

##### (a) *Cultivation Methods.*

It is important to give the best possible conditions for the growth of the crop, particularly in its early stages. Such conditions will be obtained by good cultivation, early sowing where practicable, compacting the ground to encourage root development, and by the application of superphosphate at the time of seeding so as to give the young plants a good start.

##### (b) *Rotation*

The aim of the rotation system should be to allow the infested area to remain free from a susceptible crop as long as possible. This will reduce the eelworm population in the soil. Owing to climatic features the extent to which rotation can be practised in South Australia is greatly restricted. Moreover, further knowledge is necessary regarding the susceptibility to attack of suitable rotation crops, also as to the relative susceptibility of wheat, oats, and barley. Definite information is also required regarding the influence of fallow on the eelworm population in the soil under South Australian conditions.

##### (c) *Resistant Varieties of Cereals.*

The work of Nilsson Ehle in Sweden on the varying degree of susceptibility of different varieties of barley indicates the most promising line of attack. The accumulation of systematic observations on the extent to which different varieties of wheat, oats, and barley are attacked would be most valuable. Less susceptible varieties could be worked into a rotation system, and the possibility of breeding resistant varieties could be explored.

## EELWORM, AND "NO-GROWTH" PATCHES.

[By A. R. HICKINBOTHAM, B.Sc., Dip. Ed. (Roseworthy Agricultural College).]

Towards the end of August, when most of the later-sown crops were beginning to make vigorous growth, certain "no-growth" patches (Figs. 1 and 2) appeared in the permanent rotation trials, in barley, at the Roseworthy Agricultural College.

No-growth patches have been familiar over a large area of the dryer part of the State for many years past, and they have been spasmodically investigated, but up to the present no cause has been found. Patches appear to follow the main direction of cultivation as if carried by implements, and are of limited area, those shown in the photographs being typical of those seen this season in barley. Recently a local Bureau supplied a list of 12 farms that show this trouble.

Fig. 1.—"No-growth" patch (Barley) showing stunted plants in patch.

On making a careful examination of the College rotation plots, it was seen that two plots of oats—of two acres each—were not making anything like satisfactory growth, and the plants themselves seemed to show the same characteristics as those on the no-growth patches. It seemed likely that the whole of these two oat plots were similarly but less seriously affected.

Samples of soil and affected plants were taken from two College plots and from no-growth patches on three neighboring farms. Microscopic examination of the roots of affected plants seemed to show certain ill-defined abnormalities, but the difference between these and the roots of nearby and apparently healthy plants were not marked. Mr. Garrett, of the Waite Institute, made a series of bacterial cultures without result, though several fungi were present.

Affected barley plants were transplanted into pots—some in their own soil and some in soil of a lighter type from a different area. The pots were well watered, and the plants in both soils recovered and grew strongly; those in their own soil did appreciably better. The plants, however, showed a certain robustness or stiffness in growth, and did not tiller as expected. These abnormalities were sufficiently pronounced to suggest disease in the plants themselves rather than in the soil, but, at the same time, the plants growing in their own soil showed this characteristic more markedly.

Some three weeks after the first plants were examined a further set of samples was taken, and on the roots of these minute eelworm cysts were noticed. The cysts, varying in number up to 10 or 12 per plant, were found throughout the no-growth patches. The cysts are female eelworms which have developed until they are little more than a sack of eggs—each containing 100-200. They are attached to the plant by means of the head, which is still buried in the tissues.

Fig. 2.—“No-growth” patch (Barley) showing definite margin.

Examination of the two-acre oat plots (40-50 plants were taken) showed every plant similarly affected. In the next field was a wheat crop that had been very backward in the early stages, and had been rolled and harrowed to try to promote growth. Plants were taken from this, and every plant taken showed some eelworm cysts.

The question then arose as to whether apparently normal crops had escaped the eelworm, and it was found that these also showed cysts, but a much smaller number per plant, and a correspondingly better root development.

It was soon found that almost every crop on the farm was affected; backward crops were more severely attacked. Late-sown oats, and oats on stubble, showed the heaviest infection (judged from the number of cysts showing). Fig 3 shows portion of a strip

of late-sown oats between two plots sown about a month earlier. In the late-sown plot the oats are a failure, and the bulk of the growth consists of weeds, while the earlier-sown plots appear to be normal crops. This strip contains many patches quite bare except for charlock and other odd weeds. Fig. 4 shows the roots of some of the surviving plants (and one dead plant) taken from it.

The other affected farms in the district were visited, and the no-growth paddocks proved to be similarly affected. Wheat after fallow largely seems to escape severe infection, though a few cysts are almost always found. An infected wheat field shows a patchy stand, with a gradual falling away of the crop from point to point, rather than sudden bare areas. In many fields the crop is decidedly thin, and weeds are frequently dominant over a large proportion of the area, this being the more heavily infected part.

In barley the actual no-growth patches occur with quite definite margins. Of two plants at the edge of the patch an inch apart, one may be vigorous and the other but 1 in. high (Figs. 1 and 2). These patches may not be caused by eelworm, for barley appears in many cases to make quite satisfactory growth in spite of severe infection.

Fig. 3.—Eelworm infected late-sown oats (mostly Charlock with a few surviving oat plants) with normal early crop in background.

In oats the whole field seems to be more or less evenly attacked. Most frequently no normal plants are noticed in the field. The result is that the field just appears to be a backward crop, and little or no hay is taken from it. It is recognised locally that late sowing of oats invites failure.

In one field of possibly 50 acres near Wasleys, part is in wheat and part in barley. The barley appears to be a good crop, but has numerous no-growth patches. The wheat shows the characteristic irregular stand. This was planted first with old seed and, the result not being satisfactory, it was cross drilled again with new seed. One may infer

that the plants from the old seed, having less vitality, were mostly destroyed by the eelworm. The new seed got away better, but did not escape infection. Cysts were numerous on the roots of both barley and wheat.

As stated previously, if attacked, oats seems to be uniformly and seriously infected, wheat irregularly, and barley gives largely a normal crop. A local farmer with nearly 10 years' experience of no-growth patches states that they are never serious unless barley has been grown in the paddock. If this be so, and if the patches are due to eelworm, the growth made by barley in spite of infection would probably assist the spread of the parasite, and the area might be expected to be more seriously infected after this

Fig. 4.—Roots, showing cysts, of some of surviving plants taken from strip shown in Fig. 3. The second plant has been killed.

crop. He pointed out a paddock which, as far as he knew, had never carried barley: it has been remarked that the present crop on that paddock is one of the best in the district, and though this crop proved to be affected the cysts were comparatively rare.

Comparing crops seriously infected with those less infected—judged by the number of cysts present on the roots—one cannot doubt that badly-infected crops will show a material difference in yield. In College plots now known to be seriously infected (mentioned above) the average yields have been practically 10 bush. below those obtained in the outside fields. The difference may, or may not, be due to eelworm; the point must receive serious investigation.

Many infected crops appear to recover with better growing weather, but on the College alone 200 acres of oats—mostly on stubble—have failed more or less completely, and all these crops are heavily infected with eelworm.

#### DISTRIBUTION.

To get some idea of the distribution of eelworm in this part of the State a survey was made of crops along the roads between College, Roseworthy, Freeling, Templars, College, and College, Wasleys, Mallala, Reeves Plains, College. In all 72 crops were examined along about 60 miles of road, and of these cysts were found in 70. The examination was made by pulling several small bunches of plants, and in 75 per cent. of the crops every bunch showed some cysts. In addition, many crops between College and Adelaide have been examined with similar results. The crops examined may be considered as representative of at least half a million acres, through all of which eelworm infection occurs in nearly 100 per cent. of the crops. Of the 70 infected crops 43 were wheat, 15 oats, and 12 barley. The uninfected (non-cysted) crops were one each of wheat and oats.

Fig. 5.—The effect of serious eelworm attack on root development. Matted, superficial, infected roots compared with normal penetrating roots of unaffected plants (from Freeling).

The Agricultural Instructors throughout the State were asked to examine crops in their districts and to report on the percentage of infected crops found.

Mr. W. C. Johnston, Lower North, reported that infection was widespread, and in his opinion considerable losses were being suffered throughout his district.

Mr. E. S. Alcock, South-East, stated: "This disease has been responsible for considerable reductions in returns in this district for some years."

Mr. R. L. Griffiths, Murray Mallee, stated that in 1928 it was present to some extent in a large number of crops throughout the centre and southern portions of his district, and in a few cases seriously reduced yields. In 1929 no crops were seriously affected, but this year it is again in evidence. . . . In a few cases the loss is quite serious, and some of these are on paddocks badly affected in 1928.

Mr. R. Hill, Central District, reported that he has been collecting specimens for several seasons, and that it had been detected from Victor Harbor to the lower end of Yorke Peninsula, and even on Kangaroo Island.

These facts leave no doubt as to the wide distribution of this parasite. It has been recorded previously on several occasions in South Australia, but it has never been suggested (as far as we are aware) that it was at all widespread. In fact, there seems to be no instance cited anywhere of such a widespread and uniform invasion of crops.

Fig. 6.—Rootlets showing the effect of eelworm. (Various stages).

The damage done by it, and the consequent losses suffered by farmers, can only be estimated at present: they appear to be considerable. Experiments are being commenced to obtain proof of the losses involved. Accounts from overseas indicate that they range from almost nothing to total failures according to the severity of the attack.

## RESULT OF INFECTION.

There are at least four ways in which damage results from the infection. Firstly, the minute worms live in the root tissues and extract the nourishment intended for the growth of the plant, resulting in slow and stunted growth in the early stages. When the seminal roots are infected the production of the crown roots, upon which the plant really depends, is delayed for some weeks. Once the crown roots are formed the plant seems to get away from the infection, but the check must reduce the final yield. If the plant is unable to produce crown roots, it dies.

Secondly, the affected plants make so much root growth in the surface inch or so of soil that few, if any, deep roots are produced (Fig. 5). When a worm lodges in a root, the plant to combat it produces a number of roots from that point (Fig. 6), and if these in turn are infected a tangled root system is developed at the surface, with a very limited feeding range and resistance to drought, instead of normal penetrating roots.

Thirdly, if crops are likely to be weedy the check of the plant enables the weeds to get ahead, and for the rest of the season the crop has the competition of the well-established weeds. The only weed on which the eelworm has been found as yet is the wild oat. This is occasionally infected, and no doubt often helps the eelworm to survive over fallow and pasture periods.

Finally, the damage to the root, by weakening the plant and breaking the tissues, must render it susceptible to root fungi such as take-all. It is possible that these and other fungi (which are also widely distributed) would be of much less importance if eelworm did not previously sap the vitality of plants and provide an entry into the tissues.

It may be suggested that eelworm is a seasonal affliction, and that this is an unusually bad season for it. Though this is doubtless partly true, it would hardly seem to be the case to any marked extent, since many observers state that they have seen it frequently in past seasons, but thought that it only affected small areas. It appears to have been in our soils for a long time: as far back as 1906 the late Mr. McAlpine, then Plant Pathologist of Victoria, diagnosed eelworm on specimens sent to him from this College.

The lesser problem of the relation of eelworm to no-growth patches must still be regarded as an open question. In this connection it is interesting to note that, in the communication mentioned above, McAlpine stated that eelworm was a common cause of bare patches in crops. Naturally bare patches can appear from many causes, and there seems to be no generally accepted definition of what constitutes the so-called "no-growth" patch. It has been found impossible to secure consistent descriptions of them, and it seems probable that they may be of more than one kind and, further, difficulty may arise from their having a somewhat different appearance in different cereals. There is no doubt that heavy eelworm infection and certain no-growth patches go together, but the extent to which they are cause and effect cannot be determined definitely without further knowledge of the eelworm's life history under local conditions.

The major problem, however, appears to be one of very great importance. If proportionate losses like those noted above for this area prove to be more or less general over the great portion of the State now known to be infected with eelworm, it is a problem whose successful solution is of vital importance to the whole State.

The species of eelworm found was believed to be *Heterodera schachtii*. Dr. Davidson, to whom specimens were submitted, confirmed this identification, and, at his suggestion, samples of wheat, oats, and barley showing the cyst stage have been forwarded to the Imperial Bureau of Helminthology.

## A NEW WEED (*NESLIA PANICULATA*).

[By WORSLEY C. JOHNSTON, Agricultural Instructor.]

The Roseworthy Branch of the Agricultural Bureau recently devoted a meeting to "Weeds, their Identification and Control," and among the specimens tabled by members was a cruciferous plant of the "mustard" type which was unknown to the writer.

Subsequently, with the assistance of Mr. A. J. Adams, M.A., of Roseworthy College, the weed was identified as *Neslia paniculata* (L.) Desv., and this identification was afterwards confirmed by Mr. J. G. Wood, M.Sc., Lecturer on Botany at the Adelaide University, and by Mr. E. W. Pritchard, Dip.Econ., Botanical Assistant to the Department of Agriculture. As no record could be found of its previous occurrence in South Australia, it was deemed expedient that its presence in this State should be announced.

The plant is of Mediterranean origin, and appears to be well known in North American wheat fields, where it goes under the name of "Ball Mustard," due, no doubt, to the shape of its seedpods.

The weed is a free grower, and if not controlled is capable of becoming a nuisance in cereal crops and causing great inconvenience in harvesting operations. Being similar to many of our already numerous "mustards," the method adopted for their control will be sufficient for this particular species.

Its distribution is by no means definitely known, but it has been found in the yard of the Roseworthy Railway Station, and it extends some two miles in an easterly direction and about a mile and a half north and south.

The plant is covered with stiff minute hairs which give it a rough, harsh feeling, thus making it most unpalatable to all forms of livestock.

A New Weed (*Neelia paniculata*).

## RED COMB EGG ASSOCIATION.

## OFFICIAL SINGLE TEST.

## EGG-LAYING COMPETITION, 1930-31.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1. White Leghorns—204 birds; Black Minorcas—3 birds.  
Section 3. Black Orpingtons—30 birds. Section 4. Rhode Island Reds—6 birds.

Twelve Months Test. To start on April 1st, 1930.

Section 1.—White Leghorns, 1 to 204; Black Minorcas, 205 to 207.

*Top-Dressed Pastures.*—In addition to the foregoing, 15,701 tons were used on 302,114 acres for top dressing. For details, see October (1930) *Journal*, page 252.

## WHEAT PRODUCTIVITY CLASSIFICATION, 1929-30.

With a view to ascertaining the extent of acreage producing very high and very low average returns of wheat per acre, the Government Statist has classified all wheat farms according to their productivity per acre. The accompanying return sets forth comparative details for the three seasons—1926-27, 1928-29, and 1929-30.

The total yields and averages per acre for the State for these seasons and the rainfall (April-November) were respectively 35,558,711bush., average 12.84bush., rainfall 13.40in.; 26,826,094bush., average 7.79bush., rainfall 9.39in.; 23,345,093bush., average 6.40bush., rainfall 9.57in.

Yet 2,896, 1,673, and 1,688 farmers reaped 18bush. and upwards per acre, producing 34.24 per cent., 19.69 per cent., and 27.39 per cent. of the total wheat crop from 20.14 per cent., 6.94 per cent., and 7.65 per cent. of the total area sown. The effect of the dry seasons of 1928-29 and 1929-30 is seen in the lower figures for high yields.

One of the profitable results of this analysis is the recording of the large number of farmers in all divisions of the State who succeed in getting returns from 18bush. to well over 33bush. per acre, and also the unduly large number who have reaped less than 3bush., 6bush., and 9bush., even in the best divisions of the State, thus bringing down the general average. These facts indicate the possibility in normal seasons of obtaining from a greater number of farms increased average returns per acre from the already settled wheat areas, with a consequent substantial increase in the aggregate for the State.

## ADVISORY BOARD OF AGRICULTURE.

A meeting of the Advisory Board of Agriculture was held at the Roseworthy Agricultural College, when the following members were present:—Messrs. F. Coleman (Chairman), P. H. Jones, A. M. Dawkins, H. S. Taylor, S. Shepherd, A. L. McEwin, Professor Perkins (Director of Agriculture), W. R. Birks (Principal Roseworthy College), and H. C. Pritchard (Secretary).

Apologies were received from Messrs. Geo. Jeffrey, R. H. Martin, J. W. Sandford, and A. J. Cooke.

*Experimental Plots in Semi-Arid Areas.*—The Director of Agriculture reported that arrangements had been made to conduct experiments in semi-arid areas on the property of Mr. A. J. Bartlett, Willowie.

*Water Meter Readings.*—The Secretary reported that the resolution of the Upper North Conference requesting that meter readings be posted to landowners, had been submitted to the Commissioner of Public Works, who had decided that owing to the extra cost involved the request would not be granted, but district engineers in country centres had been instructed to place the readings in letter-boxes where such were conveniently available.

*Dairy Cattle Improvement.*—The decision of the Dairy Advisory Committee that it was unable to support the request of the Southern Conference to alter the Act for the purpose of having bulls registered at nine months old instead of six months was received.

*Boxthorn and Wild Melon.*—It was decided, in accordance with a letter received from the Executive Committee of the Local Government Association, to bring under the notice of the Langhorne's Creek Branch that the Southern Conference resolution concerning boxthorn and wild melon should be referred to the Local Government Association through a district council.

*Press Reports.*—The following resolution of the Redhill Branch (dated August 5th) was read:—"That this Branch is of opinion that the associated papers are not publishing unbiased opinions of reports concerning primary producers, and we request that the Board bring this under the notice of all Branches throughout the State, or we request this to be published through the *Journal of Agriculture*." It was decided to forward a copy of the resolution to the associated papers.

### CLEARING THAT SCRUB.

CAMPBELL'S

PATENT SCRUB RAKE

WILL DO THE WORK OF 15 MEN, AND  
DO IT BETTER.

Scrub Rollers, Fire Rakes (all sizes), Tubular Sack Trucks and Bag Elevators, Wheelbarrows, Earth Scoops, Etc.

And now the famous patent  
CLOVER RAKES.

—o—

ALL PARTICULARS FROM—

**J. L. CAMPBELL & COY.,**  
147, CURRIE STREET, ADELAIDE, SOUTH AUSTRALIA.

*Fruit Buds of Apple Trees.*—Hills Conference resolution—"That the Waite Agricultural Research Institute be requested to initiate research work into the development of the fruit buds in the apple, with a view to determining as to what period the wood bud changes into the fruit bud." It was decided to refer this matter to the Chief Horticultural Instructor for a report as to whether any information is already available.

*Controlling Fruit Crops.*—Hills Conference resolution—"That steps be taken to investigate the possibility of controlling fruit crops by systematic manuring." It was decided to refer this to the Chief Horticultural Instructor for report.

*Destruction of Foxes.*—Hills Conference resolution—"That this Conference requests that considering the damage done by the fox, the month of March be set aside for the simultaneous destruction of foxes, and that it be an offence to liberate any fox." It was decided to refer this to the Minister for consideration under the Vermin Act, and that the month of February be added in the resolution.

*Sugar Industry.*—Hills Conference resolutions:—(a) "That this Conference heartily supports the action taken by the Fruitgrowers' and Market Gardeners' Association in their efforts to bring about a better position from the fruitgrowing point of view in the sugar industry"; (b) "That this Conference emphatically disapproves of the present agreement between the Commonwealth Government and the Queensland sugar interests, and strongly urges that the agreement be not renewed"; (c) "that the Advisory Board of Agriculture be requested to bring the foregoing resolutions under the notice of the Sugar Inquiry Committee appointed by the Prime Minister." It was decided to forward the resolutions to the Minister with the indorsement of the Board. Mr. Taylor voted against this motion, as he was of opinion that the resolutions should not receive the Board's endorsement. The Secretary was instructed to inform the Longwood Branch that no action would be taken with the request that a circular be sent to Branches urging them to bring the foregoing resolutions pointedly before the Federal members representing South Australia. Any action in this respect must be taken by the Branch itself.

*Opossums.*—Hills Conference resolution—"That there be no open season for opossums and that landholders be the only persons allowed to take opossums on their own property." On account of the damage which is done to lambing flocks during the open seasons for opossums it was decided to request that the opinion of the Inspector under the Animals and Birds Protection Acts be obtained on the above resolution.

*Advisory Committees.*—Hills Conference resolution—"That Branches of the Agricultural Bureau form Advisory Committees to advise new settlers coming into the district of the capabilities of land which they intend to take up." It was decided to refer this matter to next Congress so that all Branches would be able to express their views on the matter.

*Gumosis in Apricots.*—Hills Conference resolution—"That results of investigations into the cause of and remedy for gumosis of apricots be made available at the Conference of non-irrigated fruit areas at Angaston in November." The Secretary reported that the Chief Horticultural Instructor had promised to act in accordance with the resolution.

*Fallow Competitions.*—Congress resolution—"That Judges have power to award prizes in fallow competitions without taking moisture content." This was referred to the Competition Committee.

*State Bank at Alawoona.*—Murray Lands Conference resolution—"That this Conference desires to bring to the notice of the authorities the desirability of establishing a Branch of the State Bank at Alawoona at an early date in order to help the development of the district." It was decided to refer this resolution to the State Bank.

*Voting at Conferences.*—Murray Lands Conference resolution—"That at the 1931 Conference each Branch represented appoint two of their members to act as delegates to vote on business matters that come before the Conference." This arrangement received the approval of the Board.

*Cost of Wheat Growing.*—Murray Lands Conference resolution—"That the Department of Agriculture be requested to continue to carry on the work of investigating costs relating to the growing of wheat." It was decided to refer this resolution to the Director of Agriculture for report.

*Division of Conference District.*—Murray Lands Conference resolution—"That the Advisory Board be requested to consider the advisability of dividing the present Murray Mallee Lands Conference District into two Conferences." This received the approval of the Board, and the Secretary was instructed to report on how it is proposed to divide the district.

*Exchange on Cheques.*—Eyre Peninsula (Kimba) Conference—"That this Conference strongly protests against the increased exchange on cheques on Eyre Peninsula." In connection with this resolution, the Secretary read the following letter which was forwarded by the Secretary of the Associated Banks to the Miltalie Branch in July last:—"The banks note the protest of your Society, and regret that they cannot see their way clear to revert to the old rate. I am instructed to advise you that the increased rates apply only as between towns situated on Eyre Peninsula and the remainder of the State; the rates are based on the time it takes to communicate by mail with towns on the West Coast, which involves loss of interest to the banks, and on the increasing cost of maintenance of banking facilities in distant towns. I may point out that South Australia has long enjoyed rates of inland exchange which are less than those ruling in other States. The rate to be charged is 2s. 6d. per cent., with a minimum of 6d. In calculating rates over 6d. amounts of exchange will be calculated to the nearest 3d." It was decided to forward the Conference resolution to the Associated Banks.

*Conferences, Etc., on Public Holidays.*—Eyre Peninsula (Wudinna) Conference resolution—"That the Department of Agriculture be requested not to hold Conferences or Visiting Days at the Experimental Farms on public holidays." The resolution was received and noted for future action.

*Wheat in Second-hand Bags.*—Eyre Peninsula (Wudinna) Conference Resolution—"That this Conference requests the Advisory Board of Agriculture to approach the wheat merchants with a request to allow farmers to sell their wheat in good sound second-hand bags." It was decided not to take any further action in this matter.

*Price of Super.*—Eyre Peninsula (Wudinna) Conference resolution—"That Branches on Eyre Peninsula co-operate in an endeavor to present a request to superphosphate manufacturers and distributors on Eyre Peninsula to allow farmers a reduction in the price of super of the amount of commission paid to agents, provided that farmers sent in their orders direct to manufacturers." At the request of members Mr. Shepherd promised to furnish a report to the Board.

## **SUMMER FODDER CROPS**

Now is the time to sow

**SUDAN GRASS, MAIZE, MILLET, SORGHUM,  
LUCERNE, &c.**

— New Seed now Available —

**Charles Whiting & Chambers Ltd.**  
**13, PITT STREET, ADELAIDE.**

*Climatological Station at Wudinna.*—Eyre Peninsula (Wudinna) Conference resolution—"That this Conference desires to have Wudinna reinstalled as a climatological station." Referred to the Meteorological Department.

*Journal of Agriculture Subscription.*—The Secretary reported that in accordance with a resolution of the 1929 Congress, the Minister had approved of a charge of 2s. 6d. (half of the usual rate) being made to members of Branches. This arrangement dated from August 1st, and Branches have been advised that all members on the roll at that date must subscribe if they desire to receive the *Journal*. Applications for membership after the above date must be accompanied by the subscription fee, unless the nominee is a member of a family and living in the same house as a subscriber. As the *Journal* volume begins in August, the rates will be 2s. 6d. for nominations submitted from August to January, and 1s. 6d. from February to July. Life members and Branch Secretaries will be exempt from payment.

*Alteration in Name of Branch.*—The Board approved of the alteration of the name of the "Boor's Plains and Thrington" Branch to "Boor's Plains."

*New Branches.*—Approval was given to the formation of the following new Branches and foundation members respectively:—*Parrakie (Women's)*—Mesdames V. Hamdorf, Threadgold, E. Isaacson, R. Hamilton, W. Watts, F. Gravestocks, Young, A. J. Boelitz, G. Tape, H. Cabot, N. Catford, A. Lahne, J. Ferme, M. J. White, and Misses L. Boelitz and D. Hamilton; *Waddikee Rocks*—Messrs. J. W. Darby, H. C. Matthews, J. C. Higgins, C. Schumacher, H. Lavery, C. Chapman, D. F. Yares, W. V. Richardson, and E. J. Hier.

*Life Member.*—Life Membership of the Agricultural Bureau was conferred on Mr. J. M. Souter, Wirrulla.

*New Members.*—The undermentioned were approved as members of the following Branches:—*Morchard*—F. Mills; *Pinnaroo*—I. Edwards; *Tweedvale*—W. Efdmann; *Upper Wakefield*—R. Michael, B. Healey, J. Kiley, M. Kiley, jun., J. J. Ellery, E. Neumann, L. Neumann, A. Schultz, J. Simon; *Springton*—R. C. Royal; *Overland Corner*—F. Suter; *Millicent*—W. P. Merten; *Paskeville*—G. E. Meier; *Rendelsham*—A. Orchard, H. Carthew, Owen—C. Baker; *Greenock*—C. Grossman, A. Arnold, C. C. Werfel, G. Schluter; *Marama*—W. Plant, A. W. Jarrett; *Wallala*—C. Hortop, J. Lewis; *Wirrilla*—R. F. Kelly, G. Pulford; *Gladstone*—W. C. Roberts; *Wepewie*—H. W. Noske; *McLaren Flat*—R. Spriggs; *Tantanoola*—L. J. C. Osborne; *Pygery*—F. J. Brown; *Bowhill*—L. E. Tolhurst, W. H. Smith; *Koolunga*—E. T. Bentley; *Rosedale*—W. Cooper, C. Grimmett, A. Lehmann, C. Lienert; *Kalyan*—J. Sherrah; *Truro*—A. C. Tuckwell; *Blackwood*—G. A. Morphet; *Paruna*—A. E. Stribbles; *Netherton*—C. Krueger, E. R. Krueger; *MacGillivray*—W. H. Kent, W. Cooksley; *Blyth*—T. Williams, F. J. Clarke, R. Jones; *Pinnaroo Women's*—Mrs. C. O'Loughlin; *Maltee*—V. Schwarz, P. Schwarz, J. Kerin; *Wolseley*—W. Nethercott, G. Nicholls; *Wandearah*—J. W. Eagle; *Pinkawillinie*—S. W. Sampson, L. Carlson, J. Rohrlach; *Pinnaroo*—K. J. Edwards; *Renmark*—F. Townsend, J. Price, K. G. L. Vorwer; *Parilla Well Women's*—Miss Snelling; *Owen*—A. G. Bowyer; *Riverton*—Mr. R. Longbottom.

*Federal Disabilities Committee.*—The Chairman and Mr. A. I. McEwin were appointed to confer with the South Australian Committee on Federal Disabilities in the matter of arranging for witnesses and evidence to be tendered before the Commonwealth Joint Committee on Public Accounts in its inquiry on South Australia's disabilities under Federation.

*Delays in Drought Relief Payments.*—In reply to the resolution of the Upper North Conference on the question of delays in making payments for goods supplied under drought relief, a report from the Department indicated that delays were caused through certain forms not being received and through an error in names being submitted in connection with one of the payments.

*Closing of Experimental Farms.*—The following resolutions were read:—(a) Murray Lands Conference—"That this Conference views with alarm the press reports that there is a possibility of the Veitch Experimental Farm being closed, and enters a strong protest against any such action if contemplated by the Government." (b) Eyre Peninsula (Wudinna) Conference—(i.) "That the Government be requested to reconsider the proposal to close the Experimental Farms"; (ii.) "That a petition be presented to the Hon. Minister of Agriculture to carry on the Minnipa Experimental Farm on a commercial basis until such time as the financial position improves." It was decided that the Chairman and Mr. A. M. Dawkins should wait on the Minister to discuss the matter with him.

*Entires for Veitch Farm.*—Murray Lands Conference resolution—"That the Government be asked to secure two entires (Clydesdales) to be stationed at Veitch Experimental Farm, and travel the district." Further action was not taken with regard to this resolution.

*Encouraging the Breeding of Draught Horses.*—Eyre Peninsula (Wudinna) Conference resolution—"That the Government devise some scheme of encouraging the breeding of draught horses in the State." This was referred to the committee appointed to consider a previous resolution on the question of subsidising the purchase of stallions. Mr. A. L. McEwin was added to the personnel of the committee.

*Concession Freights on Flock Rams.*—Eyre Peninsula (Wudinna) Conference resolution—"That the Government be approached to assist the farmers by granting them concession freights on approved flock rams procured for the purpose of building up their flocks." It was decided to refer this to the Railways Commissioner.

*Freight Concessions on Wheat and Super.*—Eyre Peninsula (Wudinna) Conference resolution—"That the South Australian Railways be requested to reduce the freight on wheat and super on the Eyre Peninsula lines by 25 per cent. to compensate for the low price of wheat." To be referred to the Railways Commissioner.

*Pure-bred Cows for Minnipa.*—Eyre Peninsula (Wudinna) Conference resolution—"That the Department of Agriculture be requested to supply two pure-bred milking shorthorn cows to the Minnipa Experimental Farm for the purpose of breeding stock for distribution throughout this and the surrounding districts." Further action on this resolution was deferred.

*Subsidies for Crop Competitions.*—Congress resolution—"That representations be made to the Honorable the Minister of Agriculture requesting that Crop Competition subsidies be continued." Owing to the financial position it was decided not to take further action.

*Marketing of Wheat.*—Congress resolution—"That in view of the keen competition overseas and in order to improve our standard of saleable wheat we believe that the adoption of the system of branding of wheat bags similar to that in Western Australia would prove advantageous to South Australian wheat growers, and that all wheat be marketed on grade instead of the present F.A.Q." The Secretary was instructed to make further inquiries from the West Australian Department of Agriculture in regard to the working of the Act.

*Agricultural Instructors as Judges at Country Shows.*—Congress resolution—"That Instructors of the Department of Agriculture be allowed to judge at Country Shows." In view of the previous decision of the Minister it was decided not to take further action.

*Blackwood Experimental Orchard.*—Hills Conference resolution—"This meeting desires to place on record its appreciation of the good work carried on in the Blackwood Experimental Orchard, and trust that the Government finds sufficient funds to ensure continuity of this work." This resolution was referred to the Minister for his consideration.

Prior to the Board meeting the Principal of the College (Mr. W. R. Birks) conducted members over the science laboratories and several places of interest particularly associated with the experimental work of the institution.

## DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on November 3rd, 1930:—

**BUTTER.**—It is pleasing to record that owing to the continuance of spring rains in October the production of butter has been well maintained, and although the peak period of production has passed, the supplies should keep up well, as there is an abundance of feed in most districts. Values have eased from time to time because of the weakness in the London market, and as considerable shipments go forward each week, values are governed by rates obtainable there. Choicest creamery fresh butter in bulk, 1s. 2½d.; prints and delivery extra; second and third grades, 1s. 0½d. (these prices are subject to the stabilization levies); best separators, 11d. to 1s.; well-conditioned store and collectors', 8½d. to 9½d. per lb.; pastry lots lower.

**EGGS.**—Supplies of eggs have continued heavy, but with this commodity also the flush of the season is passed, and quantities are showing a slight decrease, although there is a considerable surplus still being packed for London and taken up by pulpers and picklers for winter use. Rates have continued fairly steady. Ordinary country lots, hen 5½d. per dozen, duck 6½d. per dozen; guaranteed infertile higher.

**CHEESE.**—There is still a steady improvement in quantities from the South-Eastern factories, and as a surplus is now available over and above local and interstate demands, arrangements are being made to export tonnage to London. Rates are lower than have ruled for many years past, but this applies also to all produce. New makes, large to loaf, 6½d. to 6½d. per lb.; semi-matured and matured, to 11d. per lb.

**ALMONDS.**—As usual at this time of the year there is not a great quantity of almonds being marketed as the bulk of them has been sold ere this. There is a good demand for all lines, although values eased in Brandis during the past few weeks. Brandis, 7½d. to 8d.; mixed softshells, 7d. to 7½d.; hardshells, 4d. to 4½d.; kernels, 1s. 6d. to 1s. 7d. per lb.

**HONEY.**—The demand for honey is negligible. During the month there was a little hand to mouth trade done in prime clear extracted lines, but lower grades are very difficult to quit even at low prices. Prime clear extracted in liquid condition, 4d. to 4½d.; best quality candied lots, 4d. to 4½d.; second grade, 2d. to 3d. per lb.

**BEE SWAX.**—Meeting with ready sale and prices are steady; 1s. 4½d. to 1s. 5½d. per lb., according to sample.

**BACON.**—Ample supplies of bacon have been marketed each week, and values have continued fairly steady. There is a good demand now coming in for the Christmas trade, and bacon factory small goods are also in better request. Best local sides, 10½d. to 11d.; best local factory-cured middles, 10½d. to 11½d.; large, 9d.; local rolls, 11d. to 11½d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 5d.; local hams, 1s. to 1s. 1d.; Geo. Farmer's "Sugar Cane" brand lard in packets 11d., in bulk 10d.; local lard, 10½d. per lb. in prints.

**LIVE POULTRY.**—The demand for live poultry shows an improvement due to the fact that many purchasers and produce dealers are securing their supplies for Christmas and placing same away in refrigerators; also Broken Hill buyers are operating still, and all lots submitted at the various markets each week have been readily cleared. One or two clearing sales of pure-bred poultry were held on the farms during the month, and were well attended, and satisfactory prices obtained. Prime roosters, 4s. 6d. to 5s. 6d.; nice-conditioned cockerels, 3s. 6d. to 4s. 4d.; fair-conditioned cockerels, 2s. 10d. to 3s. 3d.; chickens lower. Heavy-weight hens, 3s. 6d. to 4s. 3d.; medium hens, 2s. 10d. to 3s. 3d.; light hens, 2s. to 2s. 8d.; couple of pens of weedy sorts lower. Geese, 4s. to 6s.; prime young muscovy drakes, 4s. 9d. to 6s.; ducks, good conditioned, 3s. 9d. to 4s. 6d.; ducks, fair conditioned, 2s. 4d. to 3s. 3d.; ducklings lower. Turkeys, good to prime condition, 11d. to 1s. 2d. per lb. live weight; turkeys, fair condition, 8d. to 10d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 7½d. each.

**POTATOES.**—New Western Australian Delawares, 9s. to 9s. 6d. per cwt.; new locals, 10s. to 10s. 6d. per cwt.; Best South-Eastern and Victorian, 7s. to 8s. per cwt. ●

**ONIONS.**—Best brown, 7s. 6d. per cwt.; new white, 8s. per cwt.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

#### SOUTH-EAST DISTRICT.

##### ALLANDALE EAST.

Meeting held July 4th. Present: 15 members. The meeting was devoted to discussing arrangements for holding hay, crop, and improved pasture competitions. (Secretary, Mr. T. Earl.)

##### ALLANDALE EAST.

Meeting held August 8th. Present: 19 members. Mr. C. Winterfield contributed an interesting paper, "Early Days in the Rendelsham District." Matters in connection with local competitions were also discussed. (Secretary, Mr. T. Earl.)

##### KALANGADOO WOMEN'S (Average annual rainfall, 32.30in.).

Meeting held August 2nd. Present: Eight members. Mrs. Messenger read an instructive paper, "Floor Polishing." A good discussion followed. (Secretary, Mrs. Kennedy.)

##### KEITH (Average annual rainfall, 17.96in.).

July 24th.—Present: Eight members.

**TOMATO CULTURE.**—In the course of a paper dealing with the subject, "Tomato Growing without Artificial Watering," Mr. A. Densley said he had selected an eastern slope of sandy soil on which to grow tomatoes. The seeds were planted thinly in a large, flat box, and when the seedlings had developed three leaves they were transplanted with a piece of soil adhering to them. It was advisable to choose a dull day for transplanting and space the plants 3ft. apart. No manure was used, but all the wood ashes from the house were saved and hoed into the ground from the time of planting until the tomatoes were ready to pick. He advised picking the tomatoes directly they showed signs of coloring, when they could be put into the shed to ripen off. An important point was to keep the ground stirred, particularly after any showers of rain fell. (Secretary, Mr. C. Densley.)

##### KONGORONG.

Meeting held August 11th. Present: 12 members. Mr. E. S. Alcock (District Agricultural Instructor) delivered an address, "Sheep Diseases." The annual report was presented, and officers elected. It was decided to record in the minutes the valuable work performed by Mr. T. Morrison, who had acted in the capacity of Secretary of the Branch for 10 years. (Secretary, Mr. S. Johnston.)

##### MILLICENT WOMEN'S (Average annual rainfall, 29.70in.).

The monthly meeting was held on August 8th, there being present 11 members. The following papers were read and were responsible for instructive discussions:—"Hints on Invalid Cooking," Mrs. H. Altschwager; "The Planning of Meals," Mrs. G. Millhouse; "Cooking Fish," Mrs. L. Oberlander; "Preserving Fruit" and "Home Nursing," Mrs. Varcoe. (Secretary, Mrs. W. Varcoe.)

##### MOUNT GAMBIER (Average annual rainfall, 30.82in.).

Fifteen members and visitors attended the annual meeting, which was held on July 11th. The annual report and balance-sheet were submitted by the Secretary, Mr. G. T. Gurry, and officers elected for the ensuing year.

##### MUNDALLA (Average annual rainfall, 19.39in.).

The Annual Meeting was held on August 8th. Mr. R. Dinning occupied the chair. Addresses were delivered by Messrs. H. C. Pritchard and E. S. Alcock, of the Department of Agriculture. Twelve members were present. (Secretary, Mr. A. Ross.)

**PENOLA** (Average annual rainfall, 26.19in.).

Meeting held August 1st. Present: Seven members. A paper, "Standardisation of Primary Production," was contributed by Mr. Richardson.

The Annual Meeting was held on July 4th, there being present Mr. H. Richardson (Chair) and 10 members. The annual report was read and officers elected. (Secretary, Mr. F. Hinze.)

**RENDELSHAM.**

Meeting held August 9th. Present: 10 members and visitors. The Secretary, Mr. F. White, read an interesting paper, "The Waite Research Institute," which aroused a keen discussion.

**TANTANOOLA.**

Meeting held August 2nd. Present: Mr. R. Searle (chair) and eight members. The Hon. Secretary, Mr. H. Kennedy, read an article, "Flax Growing," which aroused an instructive discussion.

**TINTINARA** (Average annual rainfall, 18.78in.).

The meeting of July 26th was held at Messrs. Lewis Bros., Calgara Station, there being present 15 members and 19 visitors. The meeting was devoted to an inspection of the property

The meeting held on August 2nd was attended by six members and seven visitors, when Mr. H. H. Orchard (District Horticultural Instructor) gave a pruning demonstration. (Secretary, Mr. B. Fotheringham.)

**WOLSELEY** (Average annual rainfall, 18.36in.).

In the presence of 37 members and about 150 visitors, including members of the Tatiara Branch, Messrs. L. Cook, E. Alcock, H. Orchard, and W. Downes, of the Department of Agriculture, prizes were presented to the successful competitors in competitions conducted under the auspices of the Branch at a social gathering held on July 10th. Later in the month a meeting was addressed by Mr. H. Adams (Agricultural Instructor on Eyre Peninsula). (Secretary, Mr. E. Sharrad.)

**WOLSELEY** (Average annual rainfall, 18.36in.).

Mr. H. Pilgrim occupied the chair at the meeting held on August 11th, there being present 19 members. A paper, "The Value of Competitions to the Farmer," was contributed by Mr. Pilgrim. Mr. A. Grosser gave information concerning the wheat variety experiment plots being conducted on his farm. (Secretary, Mr. E. Sharrad.)

**UPPER-NORTH DISTRICT.****(PETERBOROUGH AND NORTHWARD.)****APPILA YARROWIE** (Average annual rainfall, 15.01in.).

Meeting held July 28th. Present: 15 members. Mr. E. L. Griffiths (District Agricultural Instructor for the Mallee Lands) addressed the meeting. (Secretary, Mr. E. Wurst, Appila.)

**EURELIA** (Average annual rainfall, 13.14in.).

August 6th.—Present: Eight members.

**FENCING.**—Mr. T. Brown, in reading a paper on this subject, said to make the holding vermin and sheep proof the boundary fence should be wire-netted. For posts, he recommended pine or red gum cut 5ft. 4in. long and placed 18in. in the ground. The posts should be spaced 15ft. apart, and the fence consist of two plain wires and a barb. The bottom wire should be 18in. from the ground, the next 40in., and the barb on top of the posts. Forty-two inch wire netting should be used and placed 3 in. in the ground. The netting should be tied six times between each post. Strains should be 25 posts apart. Another good fence for the boundary consisted of posts 45ft. apart with two flat iron posts, four plain, and two barb wires, the wires to be spaced as follows:—The bottom, 7½in. from the ground, the next 19in. from the ground, the next 26½in. from the ground, the next a barb 35in. from the ground, and the top wire a barb on top of the post. The barb wire should be tied to every post. A good subdivision fence consisted of posts 4ft. 9in. long placed 18in. in the ground. If plenty of timber was available the posts could be placed 15ft. apart with a strain every 25 posts. Failing plenty of timber a wooden post could be placed every 45ft. with two iron droppers between. Four plain and two barb wires should be used, the wires to be spaced as

follows from the ground:—The bottom wire 7½in., 14in., 20½in., 28½in., and the barb on top of the post. The speaker advised using the posts as soon after cutting as possible. If pine posts were allowed to dry they were inclined to split, which allowed water to enter and they soon rotted. (Secretary, Mr. E. Wall.)

**EURELIA WOMEN'S** (Average annual rainfall, 13.14in.).

August 6th.—Present: Eight members.

**CAKE AND SWEETS RECIPES.**—The following recipes were handed in:—*Sultana Cake.*—Beat ½lb. of butter to a cream and add ½lb. of sugar. Beat again and add 2 eggs, and beat for a few minutes and continue until 6 eggs have been used. Mix 1lb. of sultanas with ½lb. flour and a little essence of lemon. Stir gently into the mixture and bake for 1½ hours in a moderately hot oven. *Cream Puffs.*—½lb. butter, 1 cup of water, place in a saucepan or basin, put on the fire, bring to the boil, and then mix in 1 cupful of flour. The mixture should be fairly thick. Put aside to cool, then beat in 4 eggs, one at a time, and drop on to a cold tray one fair-sized teaspoonful of the mixture. The oven should be fairly brisk, and the mixture allowed to bake slowly. The puffs take just about 1 hour to cook. *Hard Times Cake.*—Ingredients: 3lbs. flour, ½lb. currants or sultanas, ½lb. dripping, ½lb. sugar, 1 pint yeast, and 1½ pints milk. Method—Sift flour and add currants. Put milk, dripping, and sugar on to heat, and stir until the sugar and dripping are melted. Add yeast to flour, then pour on milk and mixture and mix all well together to make a stiff dough. Set aside ready to

## METTER'S "NUOIL" DOUBLE GEARED SELF-OILING WINDMILLS.

IN SIZES FROM 6ft. TO 14ft. WHEEL.

The strongest, best lubricated, best designed, and best governed.

Pump more water on a lighter breeze.

No spring on automatic oiling system to break, and no sheet-metal oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923, 1924, 1925, 1926, and 1930 (no entry 1928-29).

Also Gold Med. All-Australian Exhibition, 1930.

A reliable and useful investment, and the popular choice of experienced pastoralists, farmers, and others.

### METTER'S 5ft. "MINOR" WINDMILLS.

Most efficient for pumping water from shallow depths.

MILL ONLY, £9 15/0; on 15ft. G.I. TOWER, £15 15/0; on 20ft. TOWER, £17 17/6.

### METTER'S FUEL STOVES AND WASHING COPPERS.

Use less fuel and retain heat longer.

WHOLLY MANUFACTURED IN SOUTH  
AUSTRALIA BY

## METTERS LIMITED,

98, 99, 100, North Terrace,  
ADELAIDE.

"NO FEAR OF A DROUGHT WITH A  
METTERS ABOUT."

rise. *Yeast*—Save the water in which potatoes have been boiled, and whilst still warm add  $\frac{1}{2}$  teaspoonful of tartaric acid, 3 teaspoonfuls of sugar, and  $\frac{1}{2}$  teaspoonful of salt. Bottle until it rises. It is advisable to use a bottle which has previously contained yeast or a small quantity of baker's yeast. *Cocoa-nut Tea Cakes*—Ingredients: 2 cupfuls flour, 1 small cup of sugar, 1 cup of milk,  $\frac{1}{2}$  cup of butter, 3 eggs, essence, teaspoonful of baking powder, and 1 cup of cocoanut. Method: Cream butter and sugar, add well-beaten eggs, a little at a time, beat well, and add flour with baking powder and cocoanut mixed. Add milk, and bake in small patty-pans until a nice brown color. This takes about 10 minutes. This mixture is sufficient for about 4 doz. cakes. *Golden Crust Sponge*—2 eggs,  $1\frac{1}{2}$  cupfuls of S.R. flour, 3 teaspoonfuls of butter, and 8 teaspoonfuls of boiling water, essence lemon. Method: Beat eggs until light, dissolve the butter in the boiling water and essence of lemon, stir in the flour, put in a sandwich tin, and bake for 10 minutes. *Ginger Sponge*—2ozs. butter, 2 eggs, 1 cup sugar,  $\frac{1}{2}$  cup treacle,  $1\frac{1}{2}$  cupfuls flour,  $\frac{1}{2}$  cup milk, a little grated nutmeg, 1 teaspoonful each of ground ginger, spice, and carbonate of soda. Beat butter and sugar to a cream, break in eggs, and beat well, add treacle and beat again, add all dry ingredients sifted together, and lastly the milk. Cook in greased sandwich tins for 20 minutes. When cold put whipped cream between layers, and cover with thin icing, and arrange pieces of preserved ginger on the top. *Almond Toffee*—2 cupfuls sugar,  $\frac{1}{2}$  cup water, dessertspoonful vinegar,  $\frac{1}{2}$  teaspoonful of essence lemon. Boil until it will harden when a little is dropped in water, pour on plates and strew with toasted almonds. *Jubes*— $\frac{1}{2}$ lb. of sugar, 1oz. gelatine, and 1 cup water. Boil sugar and water for 10 minutes, and soak the gelatine in a cup full of boiling water, then stir in the gelatine and boil for 15 minutes. Pour in 2 plates, color half with cochineal, flavor with essence lemon and pineapple. Let it stand all night in a cool place. (Secretary, Mrs. E. Wall.)

#### WARCOWIE (Average annual rainfall, 12.16in.).

The Chairman (Mr. T. Ryan) presided over an attendance of nine members and 70 visitors. Addresses were delivered by Messrs. E. L. Orchard and F. C. Richards, of the Department of Agriculture. The meeting concluded with a dance. (Secretary, Mr. A. Crossman.)

#### WEPOWIE (Average annual rainfall, 13in. to 14in.).

July 22nd.

On July 22nd members of the Branch and a large attendance of visitors, in company with Mr. W. J. Spafford and Mr. E. L. Orchard, of the Department of Agriculture, made a tour of farms in the district. Ten members and 20 visitors attended the meeting which was held in the evening, when addresses were delivered by Messrs. Spafford and Orchard. (Secretary, Mr. E. Rooke.)

#### WILMINGTON (Average annual rainfall, 17.78in.).

Mr. H. C. Pritchard (General Secretary Agricultural Bureau) delivered an address, "Keeping Farm Accounts," at the meeting held on July 15th, which was attended by 20 members and a visitor. (Secretary, Mr. G. Fraser.)

#### WILMINGTON (Average annual rainfall, 17.78in.).

Meeting held August 13th. Present: 17 members. The Secretary, Mr. G. Fraser, contributed an interesting paper, "How High Tariffs Affect the Producer."

### MIDDLE-NORTH DISTRICT.

#### (PETERBOROUGH TO FARRELL'S FLAT.)

##### BEETALOO VALLEY. (Average annual rainfall, 23.50in.).

Meeting held August 4th. Mr. H. Cook presided over an attendance of 14 members and visitors. Mr. E. L. Orchard (District Agricultural Instructor) addressed the meeting on the subject, "Crop Competitions." A programme of meetings was also arranged. (Secretary, Mr. J. Halse.)

The Annual Meeting was held on July 8th, there being present 14 members and a large number of visitors. The Secretary, Mr. J. Halse, read the Annual Report, and addresses were delivered by Messrs. H. C. Pritchard and E. L. Orchard, of the Department of Agriculture.

##### BELALIE WOMEN'S (Average annual rainfall, 17.95in.).

Mrs. Mitchell presided over an attendance of 23 members and 25 visitors. Miss E. Campbell, Dip. Dom. Econ., of the Education Department, delivered an address, "Home Dressmaking." (Secretary, Mrs. E. Orchard, Jamestown.)

**BOOLEBOO CENTRE** (Average annual rainfall, 15.4in.).

Meeting held July 21st. Present: 11 members and visitors. Addresses were delivered by Messrs. W. J. Spafford and E. L. Orchard, of the Department of Agriculture. (Secretary, Mr. C. Patterson.)

**CALTOWIE** (Average annual rainfall, 16.94in.).

July 21st.—Present: 32 members.

**TRACTOR v. HORSES.**—In collaboration with Messrs. F. Lehman and L. Catford, the following paper was read by Mr. M. Both:—"In a comparatively short time the tractor has superseded the horse in this district, and this is in keeping with the progress that agriculturists have made in other spheres. The teamster takes as one of his chief arguments in favor of horses that the tractor is not an economical investment from a national viewpoint. The fuel must come from an outside source. The extra sheep that can be carried on the farm and the extra area put under wheat as a result of the use of the tractor assume reasonable proportions when the whole State is taken into account. With my collaborators we have computed a scale for an average sized farm for this district—300 acres. Whilst the estimates have been made fairly liberal, no account has been taken of the extra labor the farmer does for the team, neither has the fact that the quality of horse teams varies greatly—the better the team the lower the costs, and *vice versa*—been considered. For hay, it has been thought that the farmer would have to let the carting or purchase a lorry. For an average distance from the town (six miles) and for this acreage (300) it was decided that the lorry would be more convenient and cheaper. Quite a large item in the costs is taxation, and if these were not taxed other sections of the farm would have to pay to balance the budget. Costs—Tractor  $6\frac{1}{2}$  per cent., depreciation 10 per cent., maintenance  $5\frac{1}{2}$  per cent. =  $22\frac{1}{2}$  per cent. on £500 = £110. Fuel, 1,000galls. at 1s. 6d. = £75; lubricant, 50galls. at 6s. = £15. Lorry,  $\frac{1}{2}$  per cent. interest, depreciation 10 per cent., tax  $2\frac{1}{2}$  per cent., maintenance 5 per cent., fuel 5 per cent. = 29 per cent. on £220—total £264. Horses—Interest  $6\frac{1}{2}$  per cent., depreciation 10 per cent., maintenance  $2\frac{1}{2}$  per cent. = 19 per cent. on £350 for 12 horses and harness = £66 10s. Interest  $6\frac{1}{2}$  per cent., depreciation 5 per cent., maintenance 2 per cent. =  $13\frac{1}{2}$  per cent. on £150 for chaff-cutting plant, binder, &c., £19 10s. Wheat off lay land, 40 acres at seven bags at 4s. bushel, £168 = total £254. These figures would vary according to the size

of the farm. A large farm would require a larger tractor, but a greater number of horses. The care of the tractor is small when compared with horses. No chaff cutting, stable cleaning, harnessing, and a host of other jobs. In dry years the horse still has to be fed, the tractor ceases to eat the moment the engine is switched off. Again, the team must be kept in working condition; feeding must be continued, though expectations of rain are not fulfilled. Also in a very dry year the lack of water might become a very serious problem. The present day tractor is so simple that little mechanical skill is required to operate and care for it between overhauls. The tractor in an indirect way lightens the task of the women on the farm. Labor troubles are practically eliminated, and the same can be said of insurance against accidents. The tractor allows more time for recreation. But perhaps the greatest advantage of the tractor is the speed of operation. In general, the tractor's speed may be said to be 30 per cent. above that of any horse team. Especially is this so during seed time and harvest. Occasionally one hears of the tractor bogging in seed time. In such cases the land should not have been worked whilst it was in that condition. The harnessing of the team and feeding at mid-day means much loss of time, which the tractor would utilise to its fullest extent. The gain for equal working hours of both is nearly half as much again in favor of the tractor. Even if the tractor does break down, the time lost in effecting repairs can be made good by the speed which the tractor has at its command. The present day spare parts service system is so efficient that the very minimum of time is lost.

**THE CASE FOR THE HORSE.**—This was the subject of the following paper read by Mr. W. Neate:—“It appears to be the general opinion to-day that farm tractors have come to Australia to stay, and if the progressive invasion of our fields and corresponding decline in the number of our draught horses were to be accepted as adequate evidence, there is at present apparent justification for this view. Nevertheless, since farming is primarily a business, however great the technical efficiency of farm tractors, and however great their attraction in other directions, they cannot hope to stay unless they can justify their use and prove that they can provide the tractive power needed on the farm at a lower cost than that provided by the horse. Although tractors appeared in Australia over 20 years ago, it is only during the last five or six years that they have come into general use. During that period we have not had an opportunity, to make a comprehensive test with the tractor against the horse under really adverse circumstances, for during this period we have not had a really wet winter. As most of the records and working costs of the tractor are taken under favorable working conditions, it would be interesting to find out how they would compare with the horse under unfavorable working conditions. My experience relative to this point is as follows:—During the seeding of 1929, under very favorable working conditions, it required 13galls. of fuel to work 30 acres, but after a rain, when the ground had become sodden and some patches boggy, it required 23galls. to drill the same acreage. This is a point that is often overlooked when comparing the two systems. At the present time it behoves us to use only those methods that tend toward the reduction of production costs. The farm tractor is handicapped at the outset on four very important points—high initial cost, rapid depreciation, liability to break down requiring costly repairs, and high fuel and oil costs. From data collected by the Department of Agriculture from 115 farmers using tractors, it was found that the average tractor of 24 B.H.P., costing £450, did the work on the farm equal to 11 horses. Taking the first point, ‘initial cost,’ let us see how they compare—one 24 B.H.P. tractor, costing £450; 11 horses at £20, £220. I have taken the sum of £20 a head for the horses, as I consider it quite possible to get together a good team at that price. The next point is depreciation. In order to fix a basis for this point, it is necessary to establish the life of a tractor. In the United States of America, from whence most of our tractors are derived, the average life of a tractor is computed at five years. Taking the useful working life of the draught horse at 10 years, this is how they compare under the heading of depreciation—One 24 B.H.P. farm tractor cost £450, average life five years, £90; 11 horses cost £220, average life 10 years, £22. It seems a rather low amount to allow on the horses, but when we consider that a horse purchased at four years will increase in value up to seven years of age, this amount is reasonable. Again, it is possible by careful handling and rearing a foal or two each year to keep the team up to standard and reduce depreciation to a minimum. It is often claimed for the tractor that it is possible, when conditions are favorable, to perform the maximum of work in the shortest time, this certainly is true and is an advantage in seeding and harvest time, but like any other mechanical appliance, this advantage is likely to be lost by breakdowns, which are serious if they occur at a critical time, involving loss of time and heavy costs for repairs. Breakdowns become more frequent as the tractor advances in years, until patching up becomes too expensive and the tractor has to be scrapped. It will be said that horses, too, are liable to ailments and accidents, but these are not usually costly in themselves, nor apart from exceptional epidemic outbreaks, is the whole team affected simultaneously; it is always possible to carry on with a horse or two short, but when anything goes wrong with the tractor the whole plant is held up. It is

claimed as cash advantages to be placed to the credit of the tractor that (1) they leave available for grain areas which in their absence would be cut for hay and fed to horses, and (2) grazing areas which, instead of maintaining horses, could be used for revenue-earning livestock, such as sheep. These advantages are no more than a set-off to the cost of fuel and oil for the tractor. These costs are also affected by the decline in wheat prices and lighter crops. With the tractor equal to 11 horses working 300 acres of crop it would be necessary to provide at least 50 tons of hay for the horses for the 12 months. In a good season a crop yielding 8 bags to the acre should cut 2 tons of hay per acre. Thus 25 acres yielding 200 bags of wheat at 5s. per bushel, £150. In a leaner year yielding 5 bags, or  $1\frac{1}{2}$  tons, it would be necessary to cut 34 acres, yielding 51 tons of hay, or 170 bags of wheat, which, at 4s. per bushel, would return £102. We would have our yearly supply of hay, but after allowing for agistment for the horses, would be at least £35 short with the tractor. One of the main reasons advanced by many farmers for scrapping their horses is to escape the drudgery connected with the horse. This is changing one form of drudgery for another; the tractor certainly needs a lot of care and attention. To the mechanically minded this work might not be irksome, yet the same could be said of the lover of the horse. The most important aspect of the tractor question is taken from a national viewpoint. Tractors, fuel, and oil we import from abroad; horses and their foodstuffs are direct products of the soil. Every drop of fuel and oil and every pound that goes towards the purchase of a tractor represents a dead loss to the district, while all that is required for the horses is the soil and the labor of our hands. We have only to take stock of our country towns since the advent of the motor car and tractors. A few years ago every town of any size boasted a blacksmith, and a saddler's shop, but to-day a large number of blacksmiths have gone out of business or turned their shop into a garage, whilst the saddler is non-existent. At that time the money made in the district was spent in the district, but now the majority is leaving the State, and this is largely responsible for the stringent financial position we are in at the present time. Another aspect of the case is the detrimental effect tractors are having on the quality of draught stock. When the demand for a good horse was keen it encouraged good judges to procure the best stallions, and their services became available in the district, with consequent improvement in our stock. I drove horses for 30 years, and although I have been wholly a tractor farmer for five years, I am strongly of the opinion that under present conditions the draught horse is the most economical source of traction on the farm." (Secretary, Mr. R. Wilkinson.)

#### KOOLUNGA (Average annual rainfall, 15.61in.).

Mr. H. Spencer presided over an attendance of 14 members and visitors at the meeting held on August 4th, when an address, "Hints on Classing the Farm Clip," was delivered by Mr. A. H. Codrington, Wool Instructor of the School of Mines. (Secretary, Mr. E. Le Page.)

#### KOONUNGA.

Mr. J. B. Harris (District Agricultural Instructor) gave a pruning demonstration and address on July 11th, there being present 25 members and visitors. (Secretary, Mr. G. C. Cartwright.)

#### MOUNT BRYAN (Average annual rainfall, 16.87in.).

On the occasion of the Annual Meeting, which was held on July 19th, the report of the year's work was presented by the Secretary, Mr. H. Edwards, and officers elected for the forthcoming session.

"isothermal layer," or the layer of equal temperature. There is the region of permanent tranquility, all weather changes, storms, &c., originating and existing below 30,000ft. Above this level blow the constant air currents which are due to dynamic causes, also controlled by the equatorial heating and the polar cooling of air above those regions. In our latitudes there is a strong westerly wind blowing just below this level. In Australia all the States as they became settled had their weather stations in operation, and in 1907 the Commonwealth Bureau was established in charge of Mr. H. A. Hunt. Forecasts are issued by each of the State Bureaux, while weather maps are published daily by nearly all the newspapers to-day. Wireless is a great aid in the issuing of special forecasts. A wireless station is situated on Willis Island off the Queensland coast, and does useful work in issuing warnings of the approach and intensity of the tropical cyclones which move towards the Queensland coast during the warm months of the year. There is no doubt that with the rapid means of modern communication and annihilation of time and distance by wireless telegraphy much will be done in the future towards the solution of the problems involved in seasonal forecasting by the accumulation and co-relation of data obtained from meteorological stations in both tropical and antarctic regions. The benefits to mankind in this connection would be inestimable. Let us examine the construction of the weather map, which appears daily in the papers, issued by the Meteorological Bureau. Scattered throughout the Commonwealth are an army of observers—postmasters, school teachers, &c.—about 5,500 in all, whose duty it is to take observations of weather conditions occurring at 9 a.m. Melbourne time. These records consist of wind direction and velocity at surface, type, altitude, and direction of various cloud layers (if any), temperatures, humidities, and, most important of all, the barometer reading. This reading is reduced to sea level, since altitude reduces the reading to the extent of in. in 900ft. It is also corrected to 32° F. since mercury expands with heat and so affects the reading. Finally, the reading is corrected to what is called standard gravity, *e.g.*, latitude 45°. This is necessary since the earth is not a true sphere, but is flat at the poles. Hence gravity is stronger at the poles or adjacent to them than it is at or near the equator. Therefore, in the construction of the weather chart all readings are corrected to the mean of the extremes, *i.e.*, Latitude 45°. Suppose we take, for example, a typical winter chart which occurred on July 6th. We shall first consider the wind directions as shown on the map by arrows flying with the wind. The arrows show that over the greater part of the continent winds were blowing around a centre situated to the north of Eucla. They were blowing outwardly from the centre, and the whole stream of air was moving in a counter-clockwise fashion. This great whirl in the atmosphere is called the "anti-cyclone," or commonly, a "high." The very name suggests an opposite system, or atmospheric whirl. On the map issued for the morning of April 4th, 1929, it is noticed that winds were blowing around a common centre, but were moving in a clockwise manner, and tended to converge into the centre, the whole stream rotating in the opposite way to the "high." This system is the "cyclone," commonly called the "low." This "low" lies over south-eastern Australia, and we can see the clockwise inward tendency of the surface winds quite distinctly. These "highs" and "lows" give all the changes and types of weather which we experience from day to day. But an even more interesting fact is shown when we take all the barometer readings sent in to the Central Bureau, and join up by a line all stations having the same corrected barometer reading. We find we have drawn a series of more or less concentric curves and circles, and these lines of equal barometric pressure are called "isobars." We see how closely the wind circulation agrees with the pressure distribution. The centre of "high" near Eucla is seen to have the highest pressure, where the central isobar reads 30.4". There the barometers on this isobar all read 30.4" after correction. Inside they are a little higher. The "low" also has its lowest pressure where the clockwise winds converge. The central isobar here reads down to 28.3". We see also that the winds appear to blow from regions of high to regions of low pressure; not directly as water does, but in a spiral manner. In the anti-cyclone is seen that the winds turn to the left as they move outwards, and so the whole system becomes a swirling mass of air tending to the left. The left-hand tendency of the winds of the high were first explained by Ferrel, who showed that, in the Southern Hemisphere a body when projected across a revolving sphere turned to the left. So a mass of air moving from high to low pressure is acted upon by this law and deflected to the left, and so flows out spirally anti-clockwise. But it is only at the surface that the spiral outflow occurs across the isobars; from 3,000ft. upwards the circulation coincides with the isobars, for here the Ferrel effect is unimpeded by friction or rising air currents off the hot earth. So we find that the high is a mass of air rotating in a counter-clockwise fashion, whose winds at the surface blow out spirally from the centre, but above the surface the circulation flows parallel to and around the isobars. The air in the centre of a high is descending, flowing down to earth where it blows out spirally as explained. This air is dry, and is warmed slightly by compression as it sinks. Hence the "high" is a fine weather system, since rain is produced by the uplifting of air. "Highs" are nearly always clear in the centre, but the eastern and

south-eastern margins are cloudy, because their winds blow from the south-west and south in front of them and bring up cold air from the Southern Ocean, which condenses the moisture in the air by cooling. A north-easterly and northerly wind on the western side blows from off the interior, and is therefore hot and dry in summer. At the centre it is calm to variable, as we would expect. In winter the rear winds of the "high" are cold, since the interior of the continent is then cold. Hence, temperature is controlled by their position. If a "high" is to the westward, cool weather occurs; if the centre is passed the winds veer northerly and temperatures rise. In summer it becomes hot, and if the "high" remains stationary in that position a heat wave occurs. "Highs" generally move from west to east about 300 miles per day, but they have a tendency to linger for long periods over the south-eastern part of the continent where the cold highlands are favorable for their existence, and frequently they increase in intensity and cause a heat wave in summer or a fine spell in winter. This winter, their persistency over this area has been most marked, causing high barometers and prolonged dry weather in South Australia. When the "highs" become very widespread and intense with barometers up to 30.6 they are very hard to displace, and

## If you can't grow vegetables

*and you can't buy them, you will  
certainly need a stock of Swallow  
and Ariell's Compressed Vegetables.*

**T**HEY'RE equal in every way to fresh, as only water is removed—true flavour is retained. One pound goes as far as ten of the fresh, so that they're easily carried. Store them as long as you like—with a few packets at hand you need never be short of health-giving vegetables.

### Here's the Range of Compressed Vegetables.

Carrots, Parsnips, Turnips, Onions, and mixed—Compressed and supplied in  $\frac{1}{4}$ lb. cartons and 1lb. tins.

Tomatoes and Rhubarb—Compressed and supplied in  $\frac{1}{4}$ lb. cartons.

Beetroot—Loose, in 1lb. tins.

Mixed Vegetables—Loose, in  $1\frac{1}{2}$ oz. packets.

# SWALLOW & ARIELL'S COMPRESSED VEGETABLES

frequently deflect "lows" in Western Australia to a south-easterly course away from their normal westerly track, which would bring rain to South Australia. Several instances have occurred this winter. The "low" or barometric depression is in all respects the converse of the "high." It rotates in a clockwise fashion whose surface winds blow into the centre spirally. In the upper levels its circulation also flows around the isobars. The air in a "low" is ascending, carrying up quantities of water vapor. As the air ascends it expands and cools, which is the principle involved in all rain and cloud production. Hence the "low" is a rain developer, and causes an unsettled state of the weather. The uprising air later flows out in the upper levels of the atmosphere about 30,000ft. near the isothermal layer before mentioned is caught in the upper westerlies and there descends to earth again down the centre of the "high" to the eastward. So there is a complete circulation going on between the two pressure systems—the surface air of the "high" being carried up through the rising swirl in the "low," to be again brought down through the descending currents of a "high." "Lows" prefer the ocean, for moisture is necessary for their existence. When they move inland they frequently lose energy and disappear. They also drift from west to east in the general drift of the atmosphere in our latitudes at an average rate of 25 miles per hour. The atmosphere has weight, and equals about 15lbs. per square inch at sea level. This weight is equalled by a column of mercury in the barometer about 30in. high. But instead of the barometers all being the same average level at all places at sea level we find that the average air pressure is greater in certain latitudes than in others. For example, along Lat. 35° S. is the belt of greatest average world pressure of about 30.05". But along Lat. 70° S. near the Antarctic Plateau lies a belt where pressure on the average reads 29.11". The region of greatest world pressure, i.e., the belt of the strongest anti-cyclones, crosses the southern half of Australia. This accounts mainly for the low rainfall of Australia and the arid drought of the interior. The other pressure belts of the world are:—The North Polar high pressure belt; the Arctic low pressure belt; the northern high pressure belt along Lat. 40° N.; the broad equatorial low pressure belt; and the Antarctic high at the South Pole. Hence, Central Australia lies too far south for the copious rains of the tropical low belt, and too far north to share in the winter rains from the Antarctic low pressure systems which surge up from the Antarctic low pressure belt. Hence, since the pressure control in Central Australia is adverse, high mountain ranges or inland lakes would not increase the rainfall there. We find similar arid regions in other countries which lie in the same high pressure belt; South America and South-West Africa in the Southern Hemisphere are almost rainless in summer, because the pressure systems are anti-cyclonic, and fail to produce rain even by cooling the winds blowing over the Andes 25,000ft. high. The three pressure belts which concern Australia are the equatorial low, the high pressure belt over Northern Australia, and the Antarctic low. These belts are not constant, but are broken up into several centres or foci, which in turn give rise to the familiar "highs" and "lows" which we have already noted. These pressure belts are not constant as regards latitude, but they swing north and south annually in accordance with the north to south swing of the sun from winter to summer. Hence in winter, as the sun apparently retreats northwards to the Tropic of Cancer, the average track of the "highs" tends to keep further inland over Australia, e.g., from Perth to Rockhampton, in mid-winter. This allows the southern "lows" to surge up and sweep the southern coastline, giving our winter rains. When, for any cause, the "highs" keep an abnormally southern track in winter, our winter rains are scanty, as the "lows" are kept well down south from our coasts. Such has been the case during the dry spell this winter. As the sun again approaches us to the Tropic of Capricorn in mid-summer, the "highs" take a course along the Southern Ocean, and the tropical lows of Australia develop to give the copious summer rainfall in the tropics. The southern "lows" are forced south again, and so the summer here is, under the control of the "highs," practically rainless. Occasionally a tropical or monsoonal "low" from the tropics drifts southwards over South Australia, and may give heavy summer rains. A very important feature of meteorology is the presence and variation of the moisture contained in the air in the form of invisible aqueous vapor. If water be exposed to the air it will sooner or later evaporate; of most vital importance is this fact in dry Australia. Only along the east and south coasts are there any places where rainfall equals evaporation. Central Australia has tremendous evaporation in a year, nearly 9ft., while the rainfall is 9in.—obviously the reason why vegetation is scanty. Boulia, in south-western Queensland, has an evaporation annually of 124.5in. Locally we average 4½ft. evaporation per year, with a 19in. rainfall. Evaporation is due to the dryness of the air. When a body of air contains all the vapor it can hold it is said to be "saturated" at that temperature. By raising the temperature we increase the amount of water vapor it can hold. By lowering the temperature we compel some of the vapor to be condensed as mist, the air of course remaining saturated. This is important, as it represents the process of cloud formation. The actual amount of vapor in the air is called the "absolute humidity," which is that portion of the barometric pressure due to water vapor in the air. In Adelaide this is

low, but in the tropics it amounts to over .5 of an inch. Relative humidity refers to the actual amount of vapor present compared with the total amount which the air can hold at that temperature. It is expressed in percentages. Saturated air, then, has a relative humidity of 100. Relative humidity is estimated from the readings obtained by the wet and dry bulb thermometers. When the temperature is low, the air cannot hold very much vapor; hence the saying "Too cold to rain" is not without scientific truth, since with low temperatures preceding the advent of a barometric depression rain development is doubtful. When warm, moist air is cooled in any way it reaches a point where it is forced to give up some of its vapor in the form of cloud. This point or temperature is called "dew-point." When water vapor is condensed from vapor to mist or liquid, a certain amount of heat is set free termed latent heat. This heat set free is a form of energy, and is largely the source of energy and violence of tornadoes which play havoc occasionally in the humid tropics. In South Australia the humidity is low, hence tornadoes are rare, and only occur when streams of tropical air flow south under certain isobaric conditions. Since rain is the most vital factor in Australian meteorology, we will now briefly refer to the principles involved in the precipitation of that priceless necessity. Rain may be developed in three ways:—(1) By the effects of convection on a hot, humid day when the heated land surface gives rise to ascending air currents which, when cooled by ascent, form the characteristic summer thunder cloud which, provided the cause is maintained, ultimately precipitates rain. (2) By coastal uplift of masses of moist air which is cooled by ascent and clouds and rain condensed. Examples occur anywhere where winds blow off the ocean over mountain ranges. (3) By the mechanical uplifting and cooling on the grand scale such as occur in the low pressure system or barometric depression. This is the way a general rain is developed, and which South Australia looks for every season. The ideal weather map for a rain of this nature in South Australia is one where an energetic "low" is located over South Australia, and is bounded on either side by two "highs," each having plenty of strength, and the eastern one maintaining its position. There is then brought about an uplifting of the air over South Australia by the action of the "low" in which the air is ascending. When this air ascends it is cooled by expansion, so that its moisture vapor is condensed into cloud. First the wispy cirrus is seen at 30,000ft., then the various other cloud types at lower altitudes until, provided the "low" does not move away too quickly, rain commences to fall, and continues more or less until the centre of the "low" passes eastward, when a shift of wind from north through west to south-west occurs, and the passing showers occur. Such uplifting of large masses of air requires enormous energy. We can judge whether a "low" or "high" is weak or strong by the number of isobars enclosing it. If several isobars enclose a low, and the central one reads 29.6, that low is fairly energetic. In the production of 1 in. of rain over one square mile it is estimated that an amount of work is expended equal to that done by 100,000,000 horsepower in half an hour. Such forces are involved in an ordinary thunder shower, while the energy required for the precipitation of a general rain over South Australia of an inch or more is utterly beyond the resources of man. Surely these facts are a complete answer to the claims of the rain maker. Rain cannot be induced to fall simply by spraying a heavy cloud with salt, or any other process. In fact a heavy cloud many thousands of feet in thickness, such as a cumulous or thunder cloud, only contains actually a few points of rain over an area equal to its base. In order to "burst" or rain a cloud must be fed from below with ascending currents. Then rain will fall as fast as it is being condensed in the rising current. If the ascent is over 20ft. per second a thunderstorm will occur; otherwise it will be purely a shower. Unless Nature is doing this work of feeding a cloud it is ridiculous to attempt to cause a cloud to rain any appreciable amount. The better an amateur can grasp the nature of the "highs" and "lows" and the behavior of the upper air movements in relation to them, the more proficient and expert will he become as a forecaster from day to day. Sir Napier Shaw says, "A modern meteorologist thinks in maps." Hence, the amateur has to take stock of the conditions around him—the movement of the barometer; the drift, type, and velocity of the various cloud layers; and the direction and strength of the surface wind, temperature, &c.—and from these construct a mental weather map to fit in with the known weather conditions; then think out from that mental map what the future weather is to be. It is quite easy to decide from these observations if our weather is controlled by a "high" or a "low," and where their centres are located, &c. By these means it is possible for the amateur to foresee practically every change at least a day ahead, and to arrive at a reasonable estimation of the probability or otherwise of rain developing by estimating the energy of the disturbance on the mental weather chart so constructed. A weak "low" may produce considerable cloud but stop at that, whereas the expert observer detects the approach of an energetic "low," and forecasts accordingly. Wind, hail, snow, heat waves, and frosts are very easy to predict by following closely the movements of the weather systems from day to day.

**BALAKLAVA** (Average annual rainfall, 15.99in.).

The annual meeting was held on July 28th, there being present 10 members. The annual report and balance-sheet was presented, and officers elected for the ensuing term. (Secretary, Mr. A. Paterson.)

**BROWNLOW.**

July 16th.—Present: 14 members.

**CARE OF HARNESS.**—Mr. T. Steinborner read the following paper:—"All harness should be attended to at least once a year. The best way to treat harness is to apply saddler's oil with a small brush. Used motor oil, lard, or fat will answer the same purpose. Oiling harness is most necessary for better and longer service, and to keep down the cost of repairs. The collar should be kept soft and smooth to avoid sore shoulders. When not in use it should be kept out of the rain and sun; a hard uneven collar is one of the chief causes of sore shoulders. To avoid confusion, each set of harness should be kept by itself. A riding saddle and a part of all reins should be treated with leather soap." In the discussion which followed a member said harness should be washed with warm water and soap before being oiled, and that should be done twice a year. Another said it was a good plan to soak a new collar in water before using the first time. The collar would then work to the shape of the horse's neck. (Secretary, Mr. T. Partridge.)

**BUCHANAN.**

Fifteen members and three visitors attended the meeting held on August 15. The annual report was read by the Secretary, Mr. L. Bell, of Marrabel, and officers elected for the ensuing 12 months.

**EUDUNDA** (Average annual rainfall, 17.19in.).

Six members attended the meeting held on July 7th. The annual report was presented and officers elected for the ensuing year. (Secretary, Mr. L. Duldig.)

**HOYLETON** (Average annual rainfall, 17.56in.).

Papers dealing with the subject, "Modern Methods of Farming," were contributed by Messrs. P. Saunders and C. Chapman, at the meeting held on July 21st, which was attended by Mr. J. Sandow (Chair) and 16 members. (Secretary, Mr. W. Chapman.)

**LYNDOCH** (Average annual rainfall, 23.71in.).

Mr. A. Springbett presided over an attendance of 21 members and three visitors. The Chairman presented prizes to the successful competitors in the recent pruning competitions. In recognition of his services as Secretary for 19 years, Mr. J. S. Hammatt, of Williams-town, was tendered a banquet and presented with a framed Life Membership Certificate of the Agricultural Bureau.

**OWEN** (Average annual rainfall, 14.22in.).

Meeting held June 10th. A large number of members and visitors attended the meeting, when Mr. B. Crewe delivered a lecture illustrated with moving pictures, "Petroleum and Its Products."

Officers were elected at the annual meeting which was held on July 11th. There were present 15 members. (Secretary, Mr. A. Bowyer.)

**ROSEDALE.**

Sixteen members and three visitors attended the meeting held on August 12th, when an interesting paper, "Fallowing and Its Benefits," was read by Mr. H. Nettlebeck. (Secretary, Mr. H. Muegge, Sandy Creek.)

**SADDLEWORTH** (Average annual rainfall, 19.65in.).

July 11th.—Present: 17 members and two visitors.

**HAND-FEEDING SHEEP.**—Mr. H. Kingston read the following paper:—"An essential part of farm management on those holdings on which sheep are carried is to make adequate provision for times of shortage for hand-feeding the flock. With the adoption of this practice, all the sheep become very quiet, and are easily handled. I give preference to feeding on grain, either oats or barley. The grain can be sprinkled on patches of hard bare ground, or in troughs constructed with flooring boards or galvanized iron. Forty feet of troughing will be found sufficient to accommodate 50 ewes, and when the lambs are from eight to 12 weeks old, additional troughing should be provided. It is important to see that sheep which are being hand fed have free access to plenty of water. Mr. F. Coleman gave a short address in which he gave an account of a trip to Queensland. (Secretary, Mr. A. Blundell.)

**TWO WELLS (Average annual rainfall, 15.88in.).**

Meeting held July 28th. Present: 10 members and visitors. Mr. B. Paech contributed an instructive paper, "Wheat Diseases." Officers were also elected for the ensuing 12 months. (Secretary, Mr. M. Pratt.)

**WASLEYS.**

Mr. E. Fischer presided over an attendance of 39 members and visitors at the meeting held on July 10th. Papers on the subject, "Motor Power on the Farm," were read by Messrs. F. Dimont and R. Richter. (Secretary, Mr. C. R. Currie.)

**WINDSOR.**

July 29th.—Present: 22 members and visitors.

On the occasion of the Annual Meeting a report of the past year's work was presented by the Secretary, Mr. R. Ford. In the course of his remarks the Secretary expressed his gratification at having been able to report a record year in the activities of the Branch. There had been an average attendance of 27 members at each of the nine meetings held during the year. Addresses were delivered by Messrs. W. C. Johnston and F. C. Richards of the Department of Agriculture.

**YORKE PENINSULA DISTRICT.****(TO BUTE.)****BOOR'S PLAINS AND THRINGTON.**

July 3rd.—Present: 25 members.

**FALLOWING.**—Mr. S. Chynoweth read the following paper:—"In the wheat belt the summer is practically rainless, and the wet season does not begin until about April. The crop is sown during May and June, and fallowing begins soon after. Thus, at least three months' wet weather normally occurs before fallowing begins, and four and possibly five months before it is finished. At first, all the rain soaks into parched soil, but sooner or later, especially during heavy falls, the soil cannot take it up fast enough. A good deal runs off the paddocks, and some lies about in shallow pools and soon evaporates. When the plough is started in July one has started early enough for first class winter fallow, but even then it is not possible to trap the rain which has run off or evaporated during the three preceding months. That can only be done by summer fallowing. Not only does summer fallow catch the early rains, but it is advantageous from several other points of view. *Summer Fallow.*—The land is opened up in February, March, or April, and lies bare for 14 or 15 months before it is sown. This method, however, cannot be employed regularly on those soils which cannot be broken up in the absence of rain; but, on the other hand, there are extensive areas which are more easily broken up dry than when wet. On very loose soils it is sufficient in the first operation to merely stir the soil 2½ in. deep with a spring-toothed cultivator. but, if necessary, the plough scarifier or a one-way cultivator will do satisfactory work. If the soil breaks up rough it is desirable to harrow it, and then it may be left until after the drilling season. The early tillage promotes a profuse germination of rubbish when the first rain comes. Sheep should be given access to the paddock, but once weeds get too far ahead it will be necessary to get rid of them by cultivation. At this stage, generally a scarifier will be equal to cutting weeds, and at the same time stirring the soil to a depth of about 2 in. or 3 in., but if a light implement is used for the first operation a plough may have to be used for the second working. Later, as rubbish appears, it must be killed by using the lightest implement that will do the job satisfactorily. As the spring advances, the aim should be to create a well-defined mulch of loose, mellow soil about 2 in. deep overlying a firmly consolidated seedbed. On soils which have a tendency to run together, the mulch should be left comparatively cloddy, but on good loamy soils, it can be fairly fine. The effect of the mulch is to reduce to a minimum the evaporation of moisture previously stored in the soil. As summer advances, an occasional "sheeping" of the fallow will suffice to prevent any oats from seeding, but should ½ in. or so of rain fall it will generally pay to give a quick harrowing to break any crust that may have formed on the surface. It is very important to recognise that a crusted surface is one through which moisture evaporates at a faster rate than through a loose surface. By permitting the crust to remain, the whole of the moisture previously stored may be lost. In the following autumn, after the weather breaks, the land can be worked up, and then, after allowing sufficient time for weeds to germinate, sown with a combined drill. Further, the germination of wheat is stimulated. Nothing better for the promotion of a good sprout of rubbish on a paddock has been discovered than to summer fallow it. Thus the system can be employed to clean up the dirtiest paddocks on the farm. When a paddock which it is intended to fallow is particularly foul with weeds it is sometimes

found desirable to restrict the first operation to a light cultivation. In this way the seeds are not buried deeply to become a menace in later years. They sprout immediately, and may be destroyed. As a word of warning to the man who is summer fallowing a dirty paddock for the first time I would say, do not do it unless you can cope early with the growth promoted, otherwise the paddock may have to be re-ploughed, and at the best an unsatisfactory result obtained. Rather than attempt to summer fallow all the land it is intended to crop, it will be most economical to treat half in that way and winter fallow the rest, thus the available labor on the farm can be most economically distributed. Some of the heavy work can be undertaken in February and March, when the teams would otherwise be idle, and the balance can be left until after seeding. The practical advantages in respect to weed killing and the distribution of labor should stamp the practice as worthy of adoption wherever it can be employed.

*Winter Fallow.*—The time has arrived when the farmer must see what can be done to increase the wheat and hay yields of his holding. Careful cultivation is the principal method of attaining this end. No hard and fast rule for the cultivation of the soil can be laid down on account of the various classes of land that are to be found, even on one farm. It is absolutely essential that every farmer should study and experiment in order to ascertain the best method of working the land on his holding. Generally speaking, ploughing should be commenced as soon as seeding operations have been completed to allow ample time for rain to play its part in the settling down of the ploughed land. Two inches to 3in. is deep enough for the land in this district to be ploughed. Do not plough the land while it is very wet, otherwise it will be very hard and lumpy when worked back with the cultivator. If the land is turned whilst very wet instead of crumbling as it is turned it will simply turn in blocks, leaving open spaces under the surface, allow the escape of moisture, and makes an imperfect seedbed. The next implement to be used is a set of heavy harrows. These should be used before a hard crust has had time to form on the surface. If no weeds appear and the surface is loose, the land should be left for a time, but if weeds show up the cultivator should be set to work at once. If weeds are small use a spring-tyne cultivator, working at right angles to the ploughing, provided the paddocks are suitable; this tends to keep the surface from becoming irregular, as happens with constant one-way working. The benefits to be obtained by using the spring-tyne implement are:—First, improvement of the seedbed; the fine, loose soil shakes to the bottom, while the coarse and more lumpy soil works to the top, thus enabling one to break it down with the harrows when rain falls. Second, lightness of draught; 10 horses are able to work a 35-tyne cultivator quite comfortably. Third, one man with 10 horses can do a great deal of work with the spring tyne. The land being left ridgy behind this implement, it has a tendency to prevent drift. If the land is free from weeds and no heavy rain falls, the land can be left until autumn. If, however, rain falls during harvesting every opportunity should be seized of working the land; summer weeds are bound to come, and the quickness of growth will cause no end of trouble. If weeds are strong and thick use a bridle cultivator with 6in. shares or a disc cultivator. Should rain fall at the beginning or up to the middle of April, it will give ample time to allow germination of weeds, and the land could be worked over before seeding. Land at seeding time should be cultivated as shallow as possible, in order not to injure the seedbed and yet deep enough to destroy young weeds. Wheat should be drilled to a depth of 1in. to 1½in. Harrow with a set of light harrows about three days behind the drill. For this district the month of May is the best seeding season, and will give best results if sown in June. Later on the ground is too cold, the seed takes longer to germinate, and the plant is weak when cold, wet weather sets in. The earlier sown crops, however, will have firmly established themselves, and will be prepared to fight against hardships. Let us all try and improve our system of cultivation. Each year do a little experimental work of this class. Read and study all papers on this subject, then we will be able to realise what there is yet to learn on this most important subject. (Secretary, S. Chynoweth, Kadina.)

---

#### KILKERRAN.

Meeting held July 29th. Present: 12 members. Mr. C. Heinrich read an interesting paper, "A Trip to the West Coast." Officers were elected for the ensuing year. (Secretary, Mr. A. Dutschke, Maitland.)

---

#### THRINGTON.

At the meeting held on August 7th, Mr. T. Stanway presided over an attendance of 24 members. The annual report and balance-sheet were read and adopted. Mr. S. Chynoweth won the trophy presented by Mr. H. Queale to the member who proposed the highest number of new members. A social evening was held on July 28th. (Secretary, Mr. S. Chynoweth.)

**WESTERN DISTRICT.****CHANDADA.**

July 18th.—Present: 18 members and four visitors.

**THE CARE AND MANAGEMENT OF THE TRACTOR.**—Mr. R. Loveday read the following paper:—“It has been frequently stated during the course of debates on the relative value of the horse and the tractor, that one great point in favor of the latter was that it could be left at the end of the day's work and, without any attention, be ready next morning for another day's work. If, however, that practice is followed to any extent, the operator will soon have plenty of trouble. The reliability and high efficiency of most modern tractors is the reason for much of the neglect from which some tractors suffer. This applies more especially when the machine is new, when the tractor is running so well that the operator is apt to become careless. The tractor, which is an expensive high grade machine, always requiring accurate adjustment of its many parts, should from the first receive regular treatment as regards lubrication, cleanliness, and adjustments. The operator should make himself thoroughly acquainted with the machine by means of the book of instructions and by careful observation when working. After a while a well-trained eye will soon detect any fault. If the operator understands the machine he can visualise the working of all concealed parts, he will realise the stresses and strains to which they are subject, and will probably drive the tractor in such a manner that the least possible strain is imparted to it. **Lubrication.**—The oil in the crank case should be changed when still in good condition. When opening the overflow tap to ascertain the oil level in the crank case, always feel the oil and note the color. Do this when the engine is warm. It is false economy not to change the oil until it has lost its body. Greasing and oiling should be done at the end of the day's work, when all parts are warm. The lubricant will then percolate freely to all parts of the bearings. Large bearings of the comparatively slow moving type fitted with greasers often retain grease better than heavy oils, especially in hot weather. It is essential that all oil and grease be kept perfectly clean. Have two grease guns, using one for grease and one for heavy oils, thus saving time in giving the correct lubricant to the various bearings. When the crank case is to be drained, have the tractor on slightly sloping ground, the tractor being inclined towards the side where the pipe plug is situated and drain after the day's work, when the engine is warm. **Ignition.**—All heavy duty engines are somewhat severe on sparking plugs and magneto breaker points. These parts should be examined regularly and adjusted. The correct gaps are—for the spark plug electrodes, 1/64th to 1/32nd of an inch; and for the breaker points from 3 to 4 millimetres. In regular working the former should be examined fortnightly, and the latter every five or six weeks. If the points are pitted, file carefully and leave the surface of the points flat and true. Oil the magneto according to instructions, and clean the breaker mechanism occasionally with petrol. The impulse starter, if inclined to stick, is a frequent source of trouble. To overcome this drill a small hole in the starter cover and either fit or solder therein a small lubricator, such as is fitted to the hub of a bicycle wheel. Kerosine or petrol can then be easily squirted through the impulse starter. **Cooling System.**—Always use clean rain water and keep the level well above the top of the tubes. Every four to six months, according to the condition of the water drain and refill, adding washing soda at the rate of 1lb. to each gallon of water. Run the tractor for a few hours with this mixture, then drain and refill with fresh water. Overheating is sometimes caused by dirty

**REVISE YOUR WILL.**

**CONDITIONS MAY HAVE CHANGED** since your Will was signed. An error or oversight may have occurred which would instantly appear now.

**PROVISION FOR YOUR WIFE**, which may have been adequate years ago, may be totally insufficient to-day.

**SATISFY YOURSELF** that your Executor is efficient and dependable, and will live to complete his duties. Many wills remain locked away for years and are not tested until after death, when it is too late to correct them.

**ELDER'S**

**TRUSTEE AND EXECUTOR COMPANY LIMITED,  
35, CURRIE STREET, ADELAIDE.**

water in the system, or a collection of dirt and foreign matter that have blocked a considerable portion of the core of the radiator. *General Adjustments.*—The valve tappets should be adjusted every three or four weeks. During heavy work this point requires particular attention. Remove the crank case, if necessary, and examine the big ends and crank case every six months. Examine cotter pins and make sure they are tight. The carburettor should be so adjusted that the engine will run on the leanest mixture that will give full power without spitting and popping back. A small jet can be used for light work and give economical results. If the machine appears to be laboring and cuts out whilst going over obstacles, fit a jet of a larger size. Set the idling adjustment of the carburettor so that when warm the engine turns over evenly and smoothly. Do not have the engine idling so that it just crawls over from one explosion to the next. This is particularly important when running on kerosine, and the engine should idle faster than if using petrol, otherwise excessive crank case dilution will result through imperfectly burnt kerosine finding its way down past the pistons. Much trouble will be avoided if all fuel is strained when poured into the tank. Steering adjustments should be correctly maintained, and always disengage the clutch thoroughly. Keep the tractor reasonably clean, so that faults can be detected, and place it under cover when not in use. *Driving.*—Loss of compression and power indicates either valve or piston ring trouble. Preferably the tractor should be driven by one man only. When starting from cold, run the engine at a fairly slow pace until warmed up a little, then open up the throttle gradually, and put the tractor to work. The sudden roaring up of the engine is too common a practice, and does considerable harm. Always engage carefully and steadily, and declutch in the same manner. Unless the driver is an expert mechanic, have the regular overhaul performed by an expert. The tractor will respond to good care and management, the same as will a team of horses. Finally, drive the machine with intelligent interest and follow the manufacturer's instructions."

#### CUNGENA, July 9th.

After the annual report had been read and officers elected, Mr. W. J. Spafford (Deputy Director of Agriculture) delivered an address, "Wheat Growing." Twenty four members and visitors attended.

A further meeting held on August 9th took the form of a "Question Box." Discussing the question as to what were the possibilities of establishing a profitable market for eggs on Eyre Peninsula, members thought that some co-operative movement would be necessary to assist in organising the scheme and packing the eggs for export. *The correct way to roll out wire netting.*—Replying to this question, a member gave the following advice:—The tight side of the netting should always be on top. An easy way to roll it out was to put a bar through the centre of the coil, then get two old drill discs and place one on each end of the bar. A small piece of rope should be placed on the outside of the discs, and the netting could then be drawn along easily. Seventeen members attended. (Secretary, Mr. H. Broad.)

#### ELBOW HILL (Average annual rainfall, 11in. to 12in.).

July 9th.—Present: Eight members and two visitors.

The meeting took the form of a Question Box. Is English malting barley any good for hay? Members had had no experience, but thought spines might be injurious. Stock ate barley stubble right to the ground. They liked it much better than wheat or oat stubbles. Barley grain was excellent feed. Points on grubbing mallee stumps? To rid land of stumps with economy one member favored a twin disc plough, especially in shoot-covered land. What are the benefits of co-operation? Mr. Coles said co-operation commenced with the first stages of life which existed between parents and children. It had wonderful power when it was worked properly. He was a firm believer in co-operation. Mr. Payne said co-operation was lacking in the farming industry, but it existed in almost every other industry to its betterment. Primary products were the mainstay of South Australia, and the buyers of these products should co-operate to protect themselves. What is the best preparation for flyblown sheep? The following preparations were recommended:—Uzona and kerosene, Vactick and drained crankcase oil and phenyle mixed. If the keeping of poultry can be proved to be remunerative, to what extent can it be developed? Members favored first-class birds, pure-bred laying strains, true to type. Red Comb eggs realised 1s. dozen more than new laid eggs. Which is the best implement for fallowing—cultivator, share, or disc plough? The disc plough was favored, mostly because of its ability to go through straw and rubbish. It also worked better in stumpy and shooty land. The cultivator was not so effective for killing weeds. (Secretary, Mr. W. Cooper.)

**GOODE WOMEN'S** (Average annual rainfall, 10.20in.).

Meeting held July 5th. Present: 14 members and three visitors. Mr. A. L. Warren (Field Officer of the Department of Agriculture) gave a lecture, "Preserving Fruit." An instructive discussion followed. (Secretary, Mrs. A. Watson, Ceduna.)

**GREEN PATCH** (Average annual rainfall, 27.56in.).

The Annual Meeting was held on July 10th, there being present 10 members. The annual report was read by the Secretary, Mr. C. J. Whillas, of Port Lincoln, and officers elected for the forthcoming year.

**KELLY** (Average annual rainfall, 11.92in.).

Meeting held July 19th.—Present: Mr. C. Freeth (chair) and 18 members. The annual report was read and officers elected. Members discussed arrangements for the forthcoming Conference. (Secretary, Mr. M. Martin, Kimba.)

**KOPPIO** (Average annual rainfall, 22.40in.).

The Annual Meeting was held at the residence of Mr. M. Gardner, there being present nine members. The annual report was presented by the Secretary, and officers elected for the forthcoming year. Supper was provided by Mrs. Gardner. (Secretary, Mr. M. Gardner, White's Flat.)

**LAURA BAY.**

Mr. C. Goddard, of the School of Mines, gave a demonstration of wool-classing at the meeting of July 29th, which was held at the residence of Mr. W. Bowell. During the evening the Annual Meeting was held. Mr. Goddard delivered an address, "The Merino Sheep," and officers were elected. Twenty-two members and eight visitors attended. (Secretary, Mr. W. Edson, Ceduna.)

**LIPSON.**

Mr. H. D. Adams (District Agricultural Instructor) addressed the meeting held on July 23rd. He explained the Egg Marketing Board that had been formed at Cowell, and stressed the value of poultry as a side line to general farming operations. Six members attended. (Secretary, Mr. M. Barraud.)

**MILTALIE** (Average annual rainfall, 13.89in.).

Meeting held July 11th, at Mr. J. Story's residence. Present: 15 members and four visitors. Mr. C. F. Anderson (Acting Poultry Expert) delivered a lecture, "Poultry Farming." Officers for the ensuing year were also elected. (Secretary, Mr. G. Smith, Cowell.)

**MINNIPA** (Average annual rainfall, 14.68in.).

Meeting held July 7th. Mr. C. A. Goddard, of the School of Mines, gave a demonstration of classing a farmer's clip.

On July 25th Mr. S. Billingham, Manager of the Experimental Farm, gave a pruning demonstration.

A further meeting was held on August 7th, when matters of local and timely interest were discussed. (Secretary, Mr. W. Crowther.)

**M. F. HODGE, A.C.I.V.****LICENSED LAND VALUATOR AND AGENT,****42, GRENFELL BUILDINGS, GRENFELL STREET, ADELAIDE.****'Phone: Cent. 3931. .. Private: Stirling 267. .. Telegrams: Matthodke, Adelaide.****SPECIALIZE IN COUNTRY VALUATIONS.****LOWEST QUOTES FOR ALL GRASS SEEDS.****LUCERNE AND CLOVERS ALWAYS AVAILABLE.****EXPERT ADVICE ON GRASSES AND CLOVERS.**

## NUNJIKOMPITA.

Meeting held July 10th. Present, 13 members and three visitors. Delegates gave a report of the proceedings of the Ceduna Conference. (Secretary, Mr. P. Luestner.)

## PALABIE.

There was an excellent attendance of members and visitors at the meeting held on July 30th, when Mr. H. D. Adams (District Agricultural Instructor) delivered an address, "Soils and Soil Analyses." (Secretary, Mr. E. Rashleigh.)

## PETINA (Average annual rainfall, 13.02in.).

Meeting held July 29th. Present: Mr. W. Schulz (chair), 15 members, and 10 visitors, including members from the Cungea and Wallala Branches. The annual report was read, and officers elected for the ensuing year. (Secretary, Mr. E. Jones.)

## PINBONG.

July 9th.—Present: 10 members.

**ELECTRICITY.**—The meeting was held at Mr. E. Kammermann's residence. The following paper was read by Mr. C. Parker:—"Electricity is one of the most fascinating studies, and there are few people who are not attracted by it. The element of mystery which surrounds it, its wonderful utility, and the many uses to which it can be put all combine to make it interesting. In addition to lighting houses and streets, electricity is now used for heating rooms, cooking, washing, haulage in buses, trams, and trains, it hews coal, saws wood, and grinds corn, &c. Electricity in small quantities can be generated for chemical action in primary batteries, such as are used to work electric bells, telegraph instruments, &c., but for large quantities it must be generated by a dynamo or generator. The current thus obtained can be led along wires and used at a distance for lighting, heating, or driving. In order to use electricity for driving purposes it is necessary to convert it into mechanical power in the form of a motor. Sometimes it is convenient to generate and distribute current in a comparatively small quantity, but at a very high voltage rather than a larger quantity at a moderate voltage, but as it is not convenient to use it either for lighting or for driving at this high pressure, another apparatus, a transformer, has to be used, which converts a small high-pressure current into a large low-pressure current. This appliance can only be used on alternating current mains. The electrical plants as used for farm purposes are usually direct-current machines. Although the initial outlay is high, these plants are a great boon to farmers; also with the aid of electrical appliances the farmer's wife can do sewing, ironing, cooking, sweeping, and washing. Also there are electric fans for hot summer evenings, and the wireless can be worked off the plant. If the electric plant is large enough the farmer can, with the aid of electric motors, work his milking machines, shearing machines, separator, and churn. Farm lighting plants are either direct coupled or belt driven. Most lighting plants for farm purposes are of 32 volts, higher voltage plants being obtainable. The 32-volt plant will light a fair number of lamps, and as the farmer only uses very few lamps at once there is always plenty of current available. The candle-power of the lamps would be in the range of 25 c.p. to 50 c.p., 32 c.p. being a good light, but for a large room a 50 c.p. lamp would be necessary. Of course, one must remember that the higher the candle-power the more current will be consumed. The amperage, or quantity of current consumed, is governed by the candle-power of the lamp. The higher the candle-power the more voluminous is the light, if voltage or pressure is in accordance with that of the lamps, therefore the higher the candle-power the more current consumed per hour. The incandescent electric lamp is very simple. When a current is forced along a conductor of any kind heat is generated into it. By using a very fine "filament" in this way it is possible to heat it to such an extent that it will give out a very bright light. If however, this was exposed to the air it would burn away instantly, so it is enclosed in a glass bulb from which the air has been pumped out. In the old-style lamps the filaments were of carbon, but the more modern lamps have metal filaments which are more efficient. In some lamps the filament is made of metal tungsten, and is supported upon a framework consisting of a glass rod with wire arms projecting from it. The whole is enclosed in a bulb from which the air has been exhausted. Tungsten is of such a nature that it cannot be drawn into a fine wire in the usual way. It is, therefore, reduced to a fine powder and mixed with some suitable binding substance into a paste, which is then forced through a small hole in a diamond so that it comes out a fine thread. This is then subjected to intense heat, which disposes of the binding material and leaves a very fine thread of pure tungsten. The exhausting of the air from the glass bulbs is a very important stage in the manufacture of electric lamps, since unless it is very thoroughly done the filaments will not last long. An ordinary mechanical pump is not good enough

as however well it is made air will escape past the piston and through the valves. Some form of mercury pump is therefore used. In these the mechanical piston is replaced by a column of mercury moving up and down in a glass tube like a barometer or else a series of drops of mercury falling down inside a glass tube acts like a number of small pistons, pushing the air before them as they fall." (Secretary, Mr. C. Scholz, Yaninee.)

#### PINKAWILLINIE.

July 12th.—Present: 19 members and visitors.

The meeting was held at Mr. S. Westover's residence. Mr. E. Atkinson gave a paper, supplemented with blackboard illustrations, reviewing the position of the average settler in the new hundreds. It was shown that although finances were embarrassed, owing to the three years of drought, the average settler had produced sound assets in the form of improvements to his property. The Secretary, Mr. S. Johnson, read the Annual Report, and the election of officers followed.

#### POOCHERA.

Meeting held July 24th. Present: Six members and several visitors. The meeting discussed the matter of holding a crop competition for the forthcoming season. (Secretary, Mr. F. Joy.)

SMOKY BAY (Average annual rainfall, 10.61in.).

A demonstration in wool classing was given by Mr. C. Goddard, of the School of Mines, in Messrs. Lovelock Bros.' wool shed at the meeting held on July 25th. There were present 17 members and visitors. (Secretary, Mr. K. Harrison.)

STREAKY BAY (Average annual rainfall, 14.95in.).

Meeting held July 25th. Present: 10 members. After the annual report had been presented and officers elected, members discussed the subject, "Bookkeeping for Farmers." (Secretary, Mr. C. Thom.)

TALIA (Average annual rainfall, 15.27in.).

Meeting held July 19th. Present: 10 members and three visitors. Matters of local interest were discussed.

A further meeting was held on August 11th. Mr. W. H. Brownrigg (District Agricultural Instructor) delivered an address, "Wheat Diseases, &c." (Secretary, Mr. A. W. Thompson, Elliston.)

#### WALLALA.

The inaugural meeting of the Branch was held on July 24th. Mr. H. Thompson presided over an attendance of 15 members and visitors, including members from the Petina Branch. Officers were elected, and Mr. W. Schulz, of Petina, addressed the meeting on the work of the Agricultural Bureau. (Secretary, Mr. C. Zippel.)

#### WIRRULLA.

An article dealing with Motor Traction was read and aroused an interesting discussion. A programme of meetings was arranged and officers elected. (Secretary, Mr. H. Doley.)

**WE ARE BUYERS AT HIGHEST MARKET PRICES**

**At Your Railway Station, Siding, or Shipping Port**

**EASTERN DISTRICT.****(EAST OF MOUNT LOFTY RANGES.)**

**ALAWOONA** (Average annual rainfall, 10.20in.).

The Annual Meeting, held on July 12th, took the form of a social evening, and was attended by a large number of members and visitors. After the election of officers, vocal and musical items were rendered, and the evening concluded with a social and dance.

A special meeting was held on July 22nd to discuss matters in connection with the Conference of Murray Mallee Lands Branches. (Secretary, Mr. B. Finey.)

**BLOCK E.**

The Annual Meeting was held on July 22nd. The annual report was presented and officers elected. (Secretary, Mr. H. Davies, Renmark.)

**BOWHILL** (Average annual rainfall, 12in.).

Twenty-six members attended the meeting held on August 4th, when Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Cultivating Mallee Soils." (Secretary, Mr. M. Banks.)

**BRINKLEY.**

Nineteen members attended the meeting held on July 23rd. Matters in connection with the Southern Conference were discussed and officers elected for the ensuing year. (Secretary, Mr. C. Pearson.)

**BUGLE.**

There was an excellent attendance of members and visitors at the annual meeting of the Branch held on July 8th. The Secretary (Mr. B. Auricht, of Taldra) presented the annual report and officers were elected. Addresses were delivered by Mr. M. Shannon, of Loxton, and Messrs. R. L. Griffiths and F. C. Richards, of the Department of Agriculture. The meeting concluded with a supper and dance.

**CALIPH.**

Meeting held July 1st. Present: Mr. S. Rundle (Chair), nine members, and three visitors. Mr. T. Flint, of the Alawoona Branch, presented a paper, "Should the Bureau Include Rural Economics in Its Field of Inquiry," which aroused a keen discussion. (Secretary, Mr. W. Todd.)

**CLANFIELD** (Average annual rainfall, 16in. to 17in.).

The Annual Meeting was held on July 10th. Delegates were appointed to represent the Branch on the Chandos Crop Competition Committee. Officers were elected for the ensuing year. (Secretary, Mr. W. Pearce.)

**COPEVILLE** (Average annual rainfall, 11.58in.).

Mr. J. Collins presided over an attendance of 11 members and a large number of visitors at the meeting held on July 9th, when Mr. C. McKenna, B.V.Sc., M.R.C.V.S. (Government Veterinary Officer), delivered an address, "Common Ailments of Farm Stock." (Secretary, Mr. G. Sutherland.)

**COOMANDOOK** (Average annual rainfall, 17.45in.).

Annual Meeting held July 25th. Present: Mr. F. Ballard (Chair) and nine members and two visitors. The annual report was read and officers elected. (Secretary, Mr. W. Trestrail.)

**KALYAN.**

Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Wheat Diseases," at the meeting held on July 15th. (Secretary, Mr. V. Luhrs.)

**KANNI.**

Meeting held July 12th. Present: 18 members. The annual report was read and officers elected for the ensuing year. A programme of meetings was also arranged. (Secretary, Mr. F. Woodhead, Waikerie.)

**KI KI.**

The meeting held on July 23rd was attended by the Chairman, Mr. W. Goodall, 10 members, and several visitors. Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Suitable Wheats for the District." (Secretary, Mr. P. Crowhurst.)

**MARAMA.**

The Annual Meeting was held on July 21st, and was attended by 14 members and visitors. The annual report was presented by the Secretary, Mr. T. Hinkley, and officers elected for the ensuing year.

**MERIBAH** (Average annual rainfall, 11.70in.).

Mr. W. Mason presided over an attendance of 23 members at the meeting held on July 14th when Mr. E. L. Griffiths (District Agricultural Instructor) delivered an address, 'Fallowing and Cultivation.' (Secretary, Mr. E. Carr.)

**MILLENDILLA** (Average annual rainfall, 13in.).

Eight members and several visitors were present at the Annual Meeting, which was held on July 17th. The Secretary, Mr. V. Wegener, read the annual report, and the election of officers took place.

**MONARTO SOUTH** (Average annual rainfall, 14in. to 15in.).

July 19th.—Present: 30 members.

**CROP ROTATION.**—The following paper was read by Mr. H. Kempe:—"It is possible to grow wheat on the same land every year. This practice is adopted for a few seasons when a farmer is taking up virgin country to assist him to obtain as much as possible from his land. This state of affairs, however, cannot continue for any length of time. It is claimed, for instance, if a cow be left in a clover field, having nothing else to eat but clover, the time will quickly come when she will sicken of this food. The same may, in a measure, be applied to a plant. The following are the advantages of a good rotation:—It Conserves Plant Food.—The toxins produced by one plant in many cases are an advantage to another plant. This is readily seen where one crop stimulates one kind of weed to grow beside it; the residue left by one plant becomes food for another. It Economises Manure.—Some crops require more of one constituent, e.g., potatoes require much potash and cereals little, so that by interposing potatoes between cereals a better use can be made of the potash in the soil. Again some crops are deeper rooted draw supplies from the subsoil, e.g., wheat or rape, while others are shallow, e.g. barley or turnips. Thus in a rotation all layers of the soil are brought into active commission. It Conserves Moisture.—By rotating some crops require more cultivation than others, and it is an acknowledged fact that cultivation is the secret of dry farming. Water is also conserved when the rotation includes a well-cultivated bare fallow. It Improves Cultivation.—Many crops give opportunity for intertillage of the soil. It Restores Humus.—The humus in the soil can be replenished by the growth of forage crops, which may either be ploughed in as green manure or consumed on the land by stock. Nothing can compensate for the absence of humus, and by introducing green crops into a rotation whose main object is the production of wheat, the yields of wheat may be largely increased. Humus is the decaying vegetable matter of soils, and is replenished by the addition of crop residues or stable manure. Humus, when decayed, eventually forms nitrates, which are essential to successful cropping. The oxidation or decaying process of humus is brought about by various kinds of bacteria and free access of air. In damp soils, in the absence of air, the bacteria cannot complete the process of decomposition, with the result that 'humid acids' are formed, rendering the soil sour. In such cases lime is useful, because it stimulates the bacteria that decompose the humus. Generally speaking, the more pervious to air a soil is, such as sand, the more rapidly will the humus be changed into nitrates, and the more frequently will the humus require renewing. It Replenishes Nitrogen.—Leguminous crops can be grown at some place in the rotation, and thus a store of nitrogen is laid up in the soil for the use of future crops. It Eradicates Weeds.—Weeds are kept down when the rotation contains bare fallow or a crop grown in wide drills, permitting intertillage, thus keeping down weeds. Checks Disease.—Oats, for instance, are not affected by take-all, neither are peas, trefoil, or clover. As this fungus cannot live without food, a suitable rotation will help considerably to check this disease. It permits of keeping livestock. It Distributes Labor.—Different crops have different seasons of sowing and harvesting. On a one-crop farm, however, certain seasons are too slack, whilst others are too busy. Where constant labor cannot be found the hired help obtained at the busy season is often not satisfactory. It Tends to Decrease Market Fluctuations.—A rotation of crops gives a variety of produce, and in a bad year for the selling of wheat it is possible that the market for wool, mutton, dairy produce, &c., may be better, thus keeping up the gross receipts. To select the particular rotation which is suited to his locality is a very important task which falls to the lot of the farmer. In dry districts special attention should be given to fallowing and the conservation of soil moisture, and in planning a rotation this fact should be constantly kept in view. Following examples of rotation might be suggested

for practice in dry districts:—A—Wheat—pasture—bare fallow; B—Wheat—bare fallow—rape (or any other forage crop, such as peas, &c.)—bare fallow. This rotation would permit of the carrying of much larger flocks. For a rainfall of from 15in. to 20in. one fallow would probably do for every two crops, and the following rotation could be adopted:—A—Wheat—rape—bare fallow; B—Wheat—bare fallow—rape. Here again in place of rape some other forage crop could be chosen." Discussing the paper members were of opinion that oats should be substituted, for conditions were too dry for the latter crop in the Monarto district. (Secretary, Mr. C. F. Altmann.)

#### MOOROOK.

The Secretary of the Branch, Mr. E. Liddicoat, reports that meetings of the Branch have been held as follows:—June 5th, Mr. H. Berriman (District Horticultural Instructor) gave a pruning demonstration. On June 10th the local pruning competitions were held. Mr. F. Petch gave an address, "Ailments of Stock," at the meeting held on July 22nd, which was attended by 14 members. On August 14th Messrs. H. B. Barlow and P. H. Suter, of the Dairy Branch of the Department of Agriculture, addressed a gathering of 24 members and visitors on the subject, "Keeping Cows on an Irrigated Fruit Block."

#### NETHERTON.

Twenty-two members attended the meeting held on July 9th. The following papers were read and discussed:—"Farming with the Tractor," Mr. W. Merritt; and "Farming with Horses," Mr. A. Ritchie. (Secretary, Mr. C. Wilkin, Yumali.)

#### NUNKERI.

Business of a formal nature was transacted at the meeting held on July 9th, which was attended by Mr. R. Elliot (Chair) and 12 members. (Secretary, Mr. F. Ling.)

#### OVERLAND CORNER (Average annual rainfall, 10.58in.).

Mr. T. Atkinson presided over an attendance of 17 members at the annual meeting held at Mr. J. Loffler's residence on July 8th. The annual report was read and officers elected. A programme of meetings was arranged. (Secretary, Mr. H. A. Loffler, "Wirrilyerna," via Morgan.)

#### PARILLA WOMEN'S (Average annual rainfall, 14.15in.).

July 29th.—Present: 17 members.
